

# High-order CFD and Multiscale Modelling for Aerospace and Nanotechnology Applications

**Dimitris Drikakis**

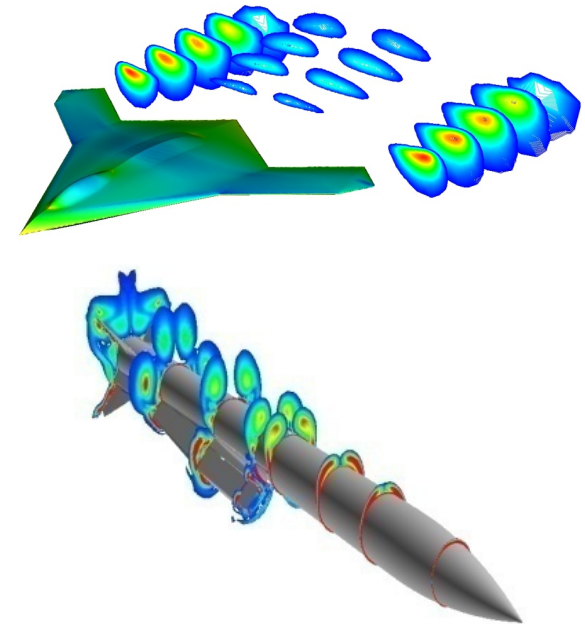

*Fluid Mechanics and Computational Science Centre  
Institute of Aerospace Sciences  
Cranfield University, UK*

Acknowledgements (PhDs and RAs): A. Antoniadis, M. Frank, M. Kio, I. Kokkinakis, Z. Rana, P. Tsoutsanis

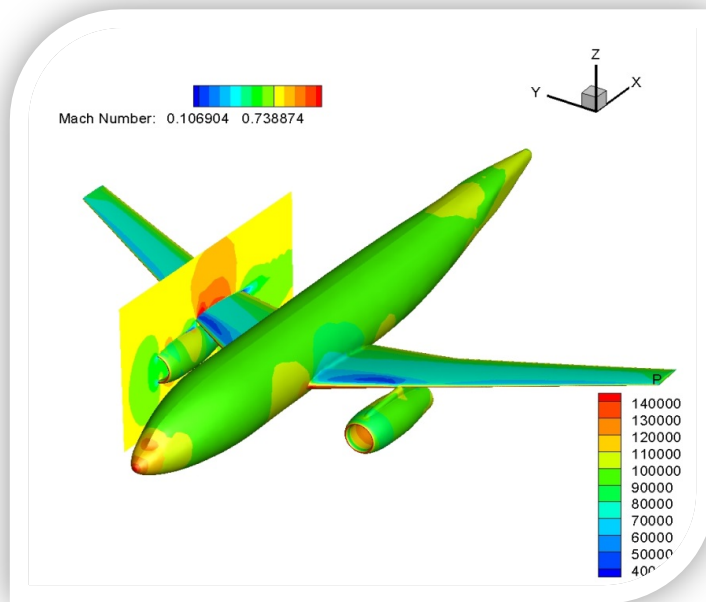

Applied Modeling & Simulation Seminar Series  
NASA Ames Research Center, August 28, 2014

# Motivation

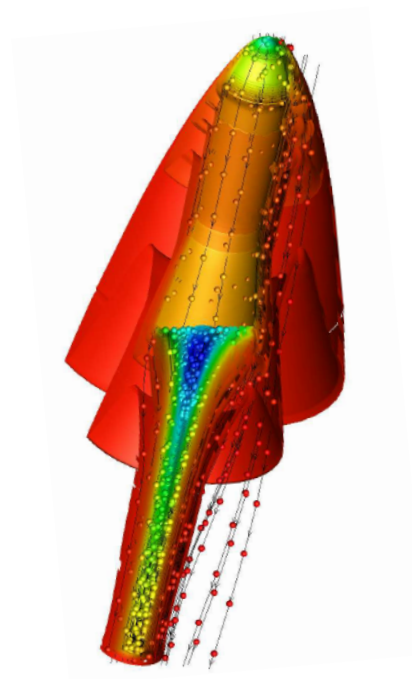

- ❑ Advances in computational methods have increasingly enabled the simulation of complex flows, heat transfer, acoustics, and fluid-structure interaction phenomena.
- ❑ Advances in high performance computing (HPC) have allowed more complex simulations to be performed at shorter turn-around times.
- ❑ However, the design and condition monitoring of advanced aerospace systems increasingly require more detailed and accurate understanding of complex phenomena and conditions at all scales.
- ❑ Reducing the uncertainty in engineering simulations by increasing the accuracy, while making computations more efficient still remains a scientific challenge

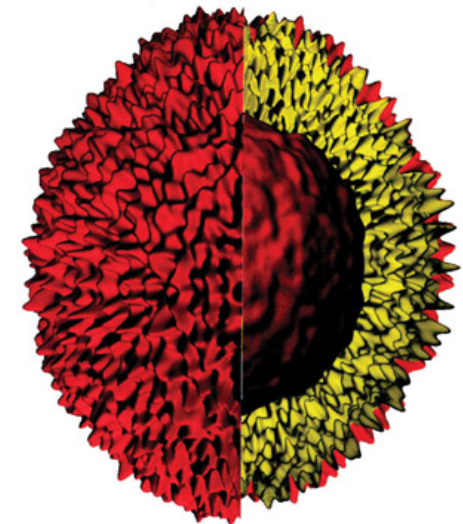

# Diverse applications

Subsonic and transonic

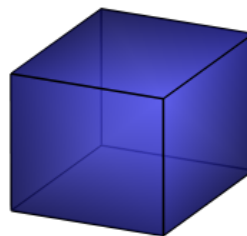

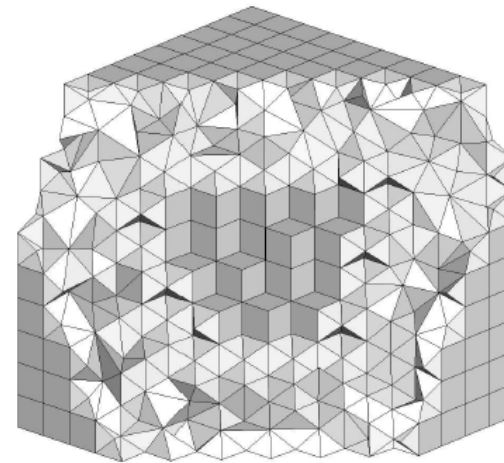

High-speed

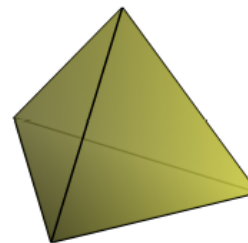

Inertial Confinement Fusion

# Unstructured grids

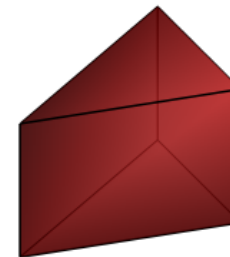

- ❑ Consist of different types of element shapes to improve efficiency in representing complicated geometries accurately by using the minimum number of cells
- ❑ Prismatic and Hexahedral elements ideal for being used in the boundary layer region

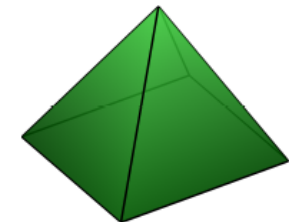

(a) Hexahedral

(b) Tetrahedral

(c) Prism

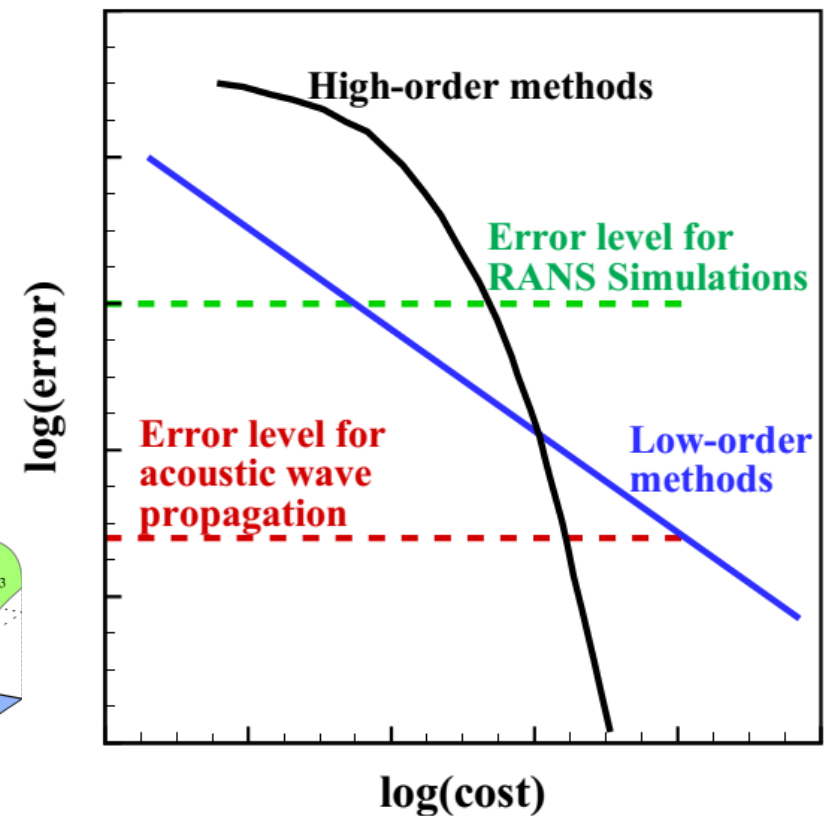

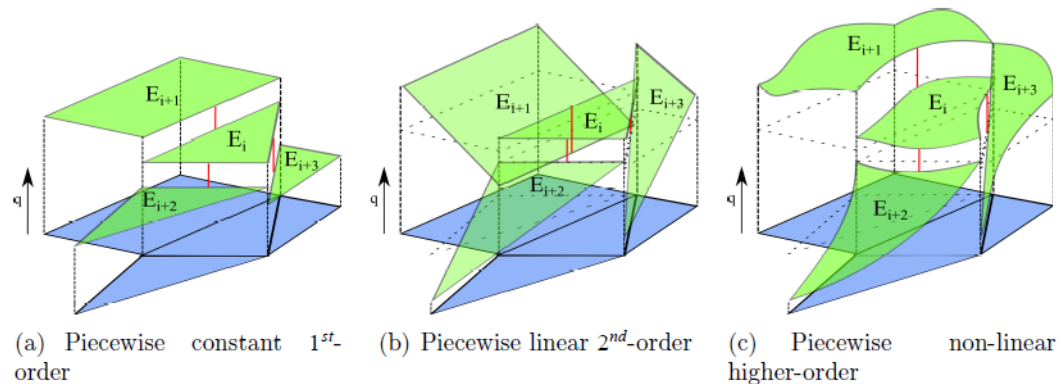

(d) Pyramid

Figure 3.1: Convex polyhedrons

# Spatial discretisation

- ❑ High-order of accuracy obtained by performing an interpolation (reconstruction) using the cell averages of the neighbourhood of considered cell
- ❑ Legendre type of polynomials employed for this purpose

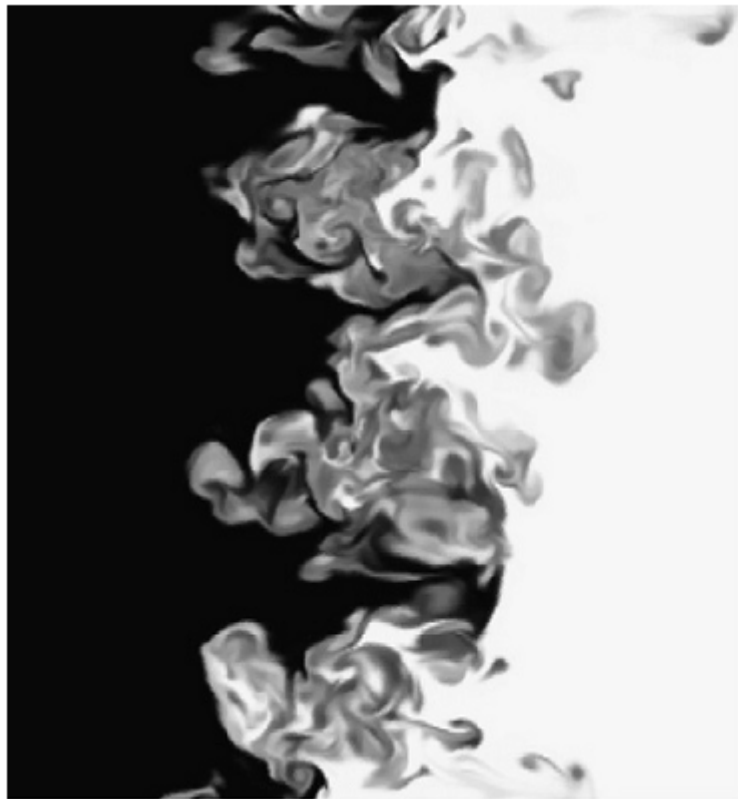

Error vs cost for high and low-order methods

# Low Mach Corrections

Example: Compressible Turbulent mixing,  
Richtmyer-Meshkov instability

5<sup>th</sup>-order method

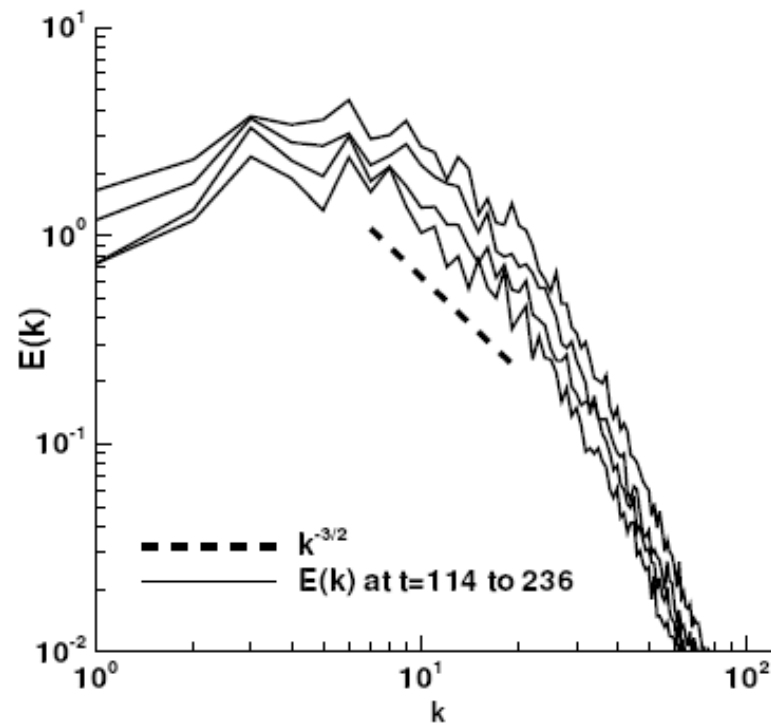

5<sup>th</sup>-order +  
low Mach corrections

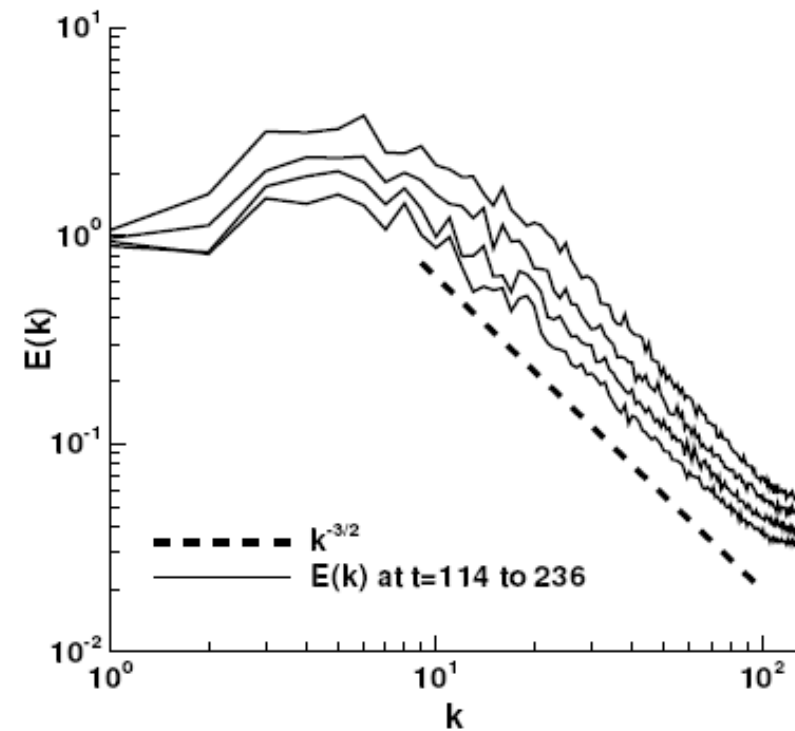

# Effects on turbulence spectrum

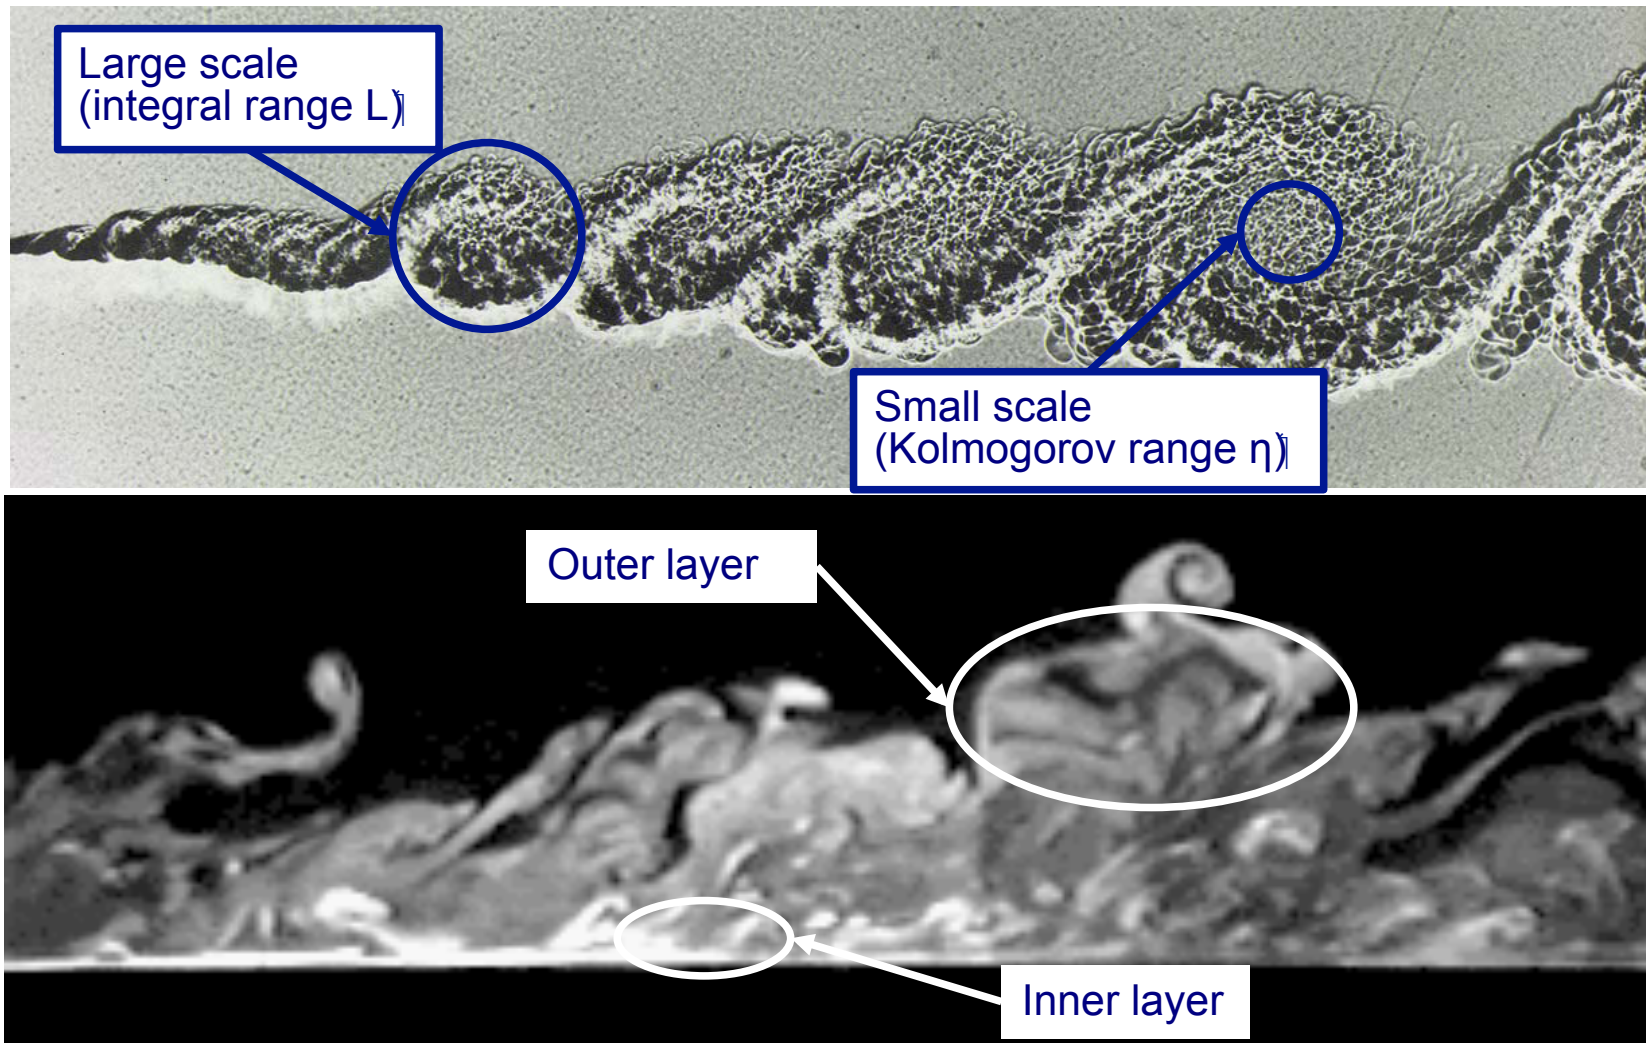

5<sup>th</sup>-order method

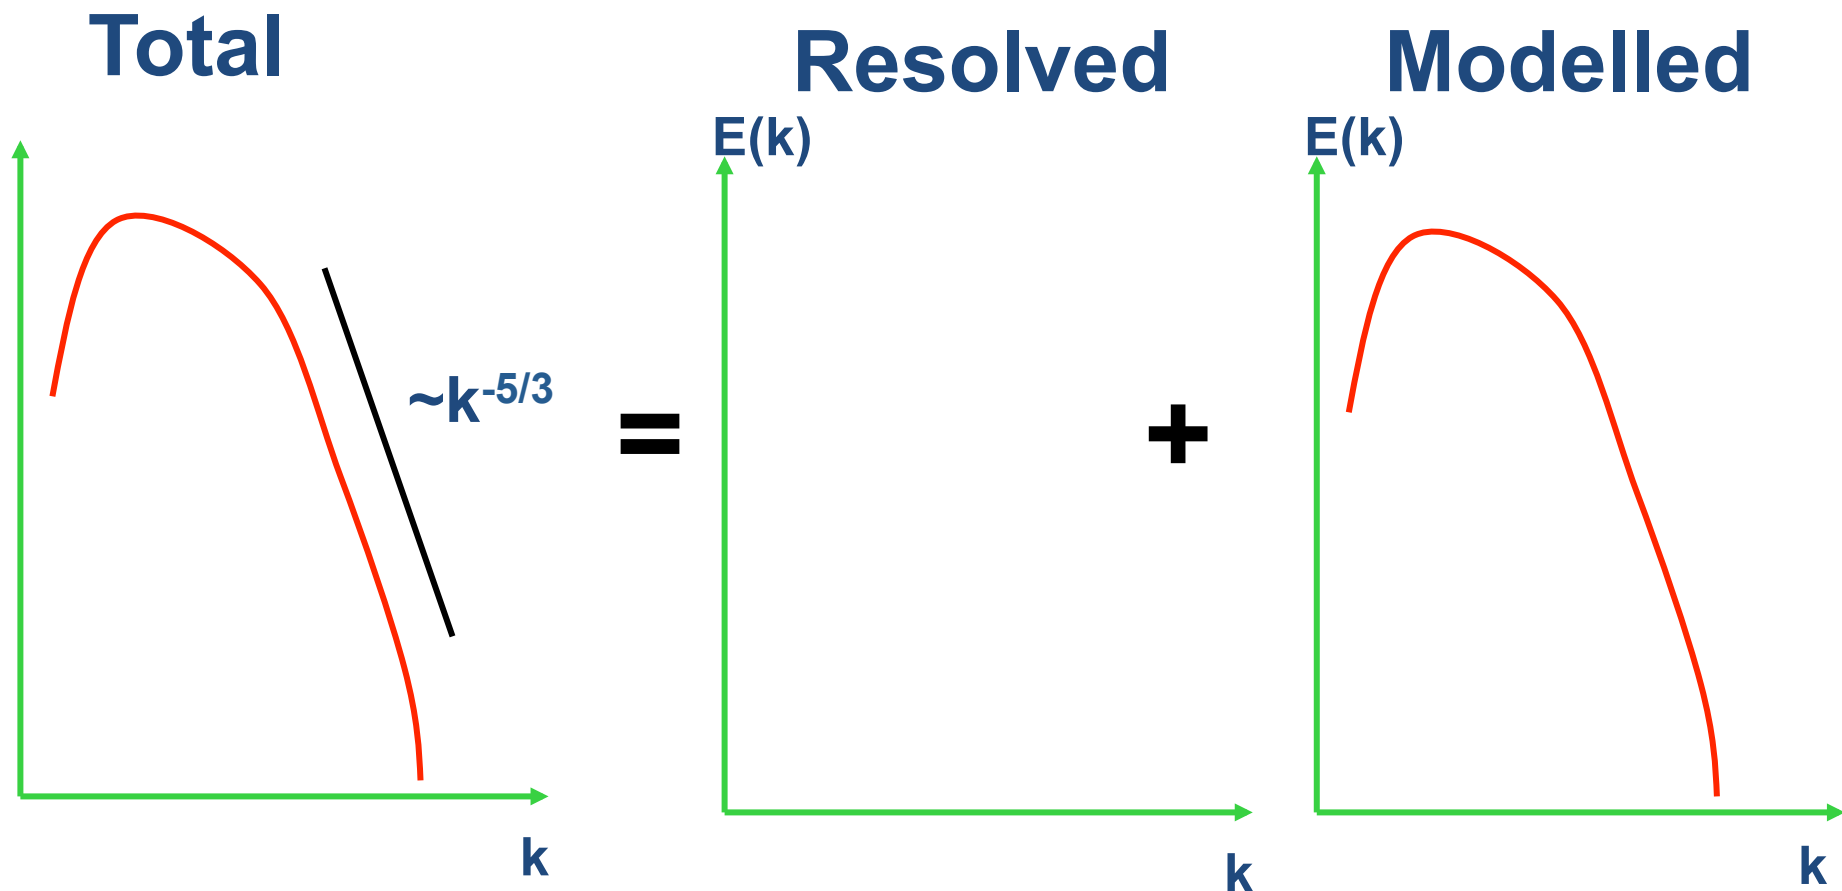

5<sup>th</sup>-order +  
low Mach corrections

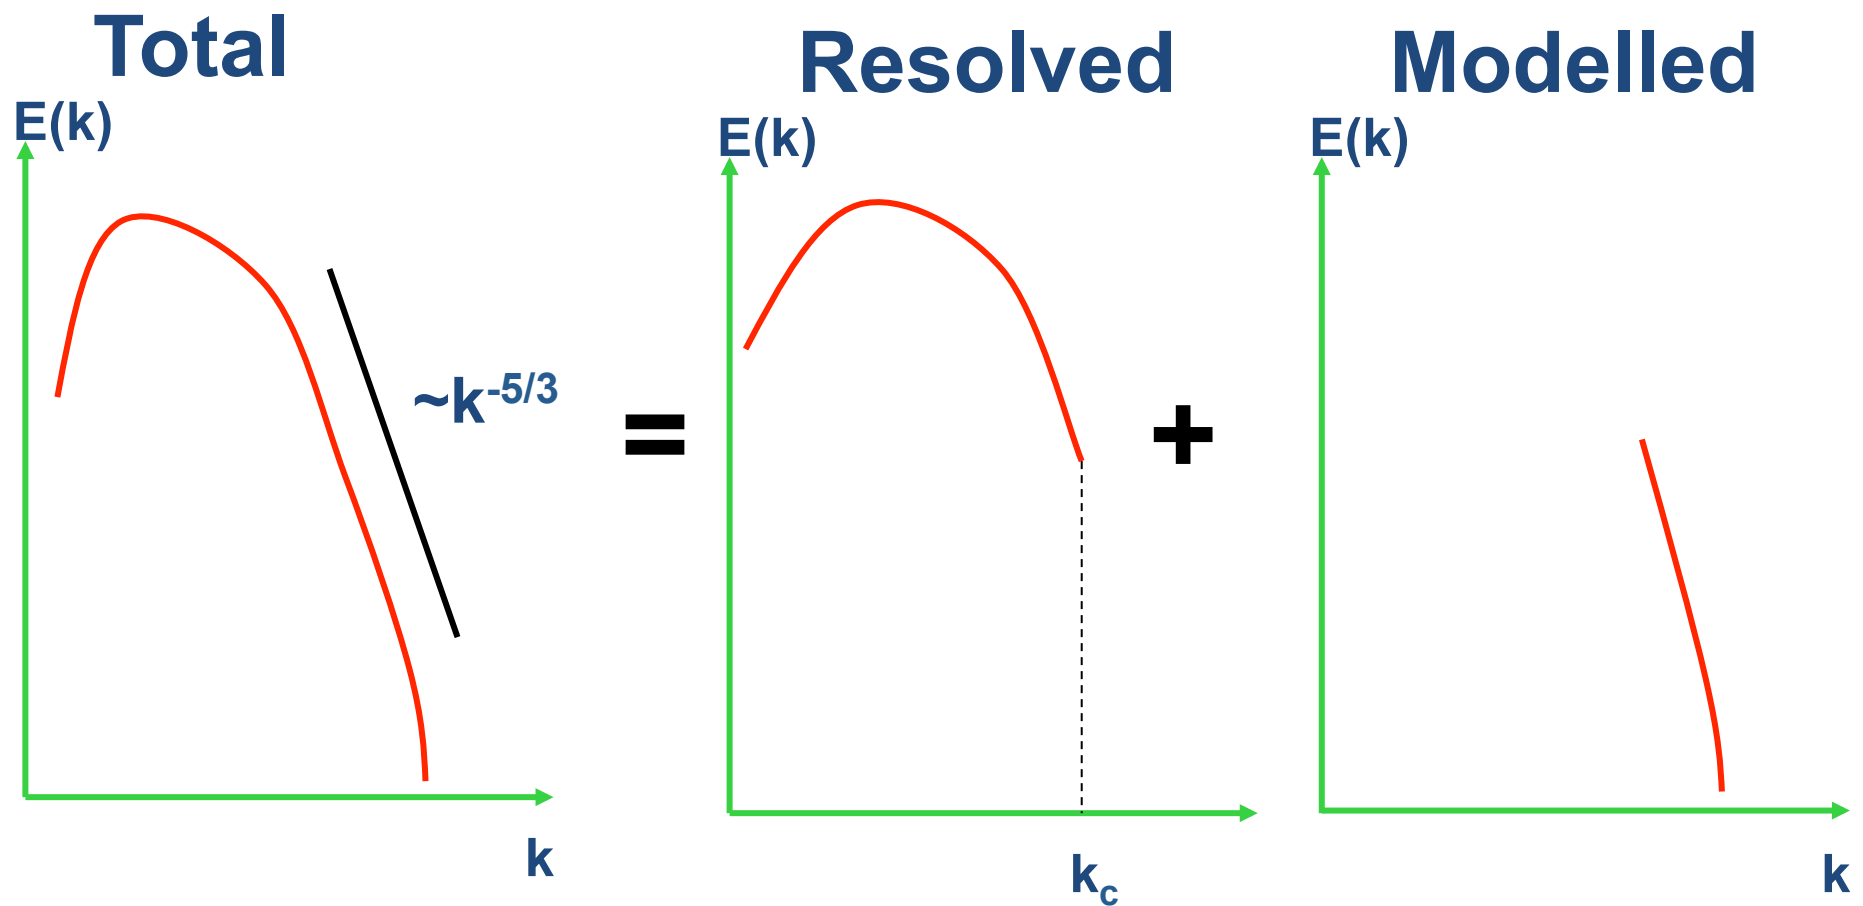

# Rationale for different Turbulence Simulation Approaches

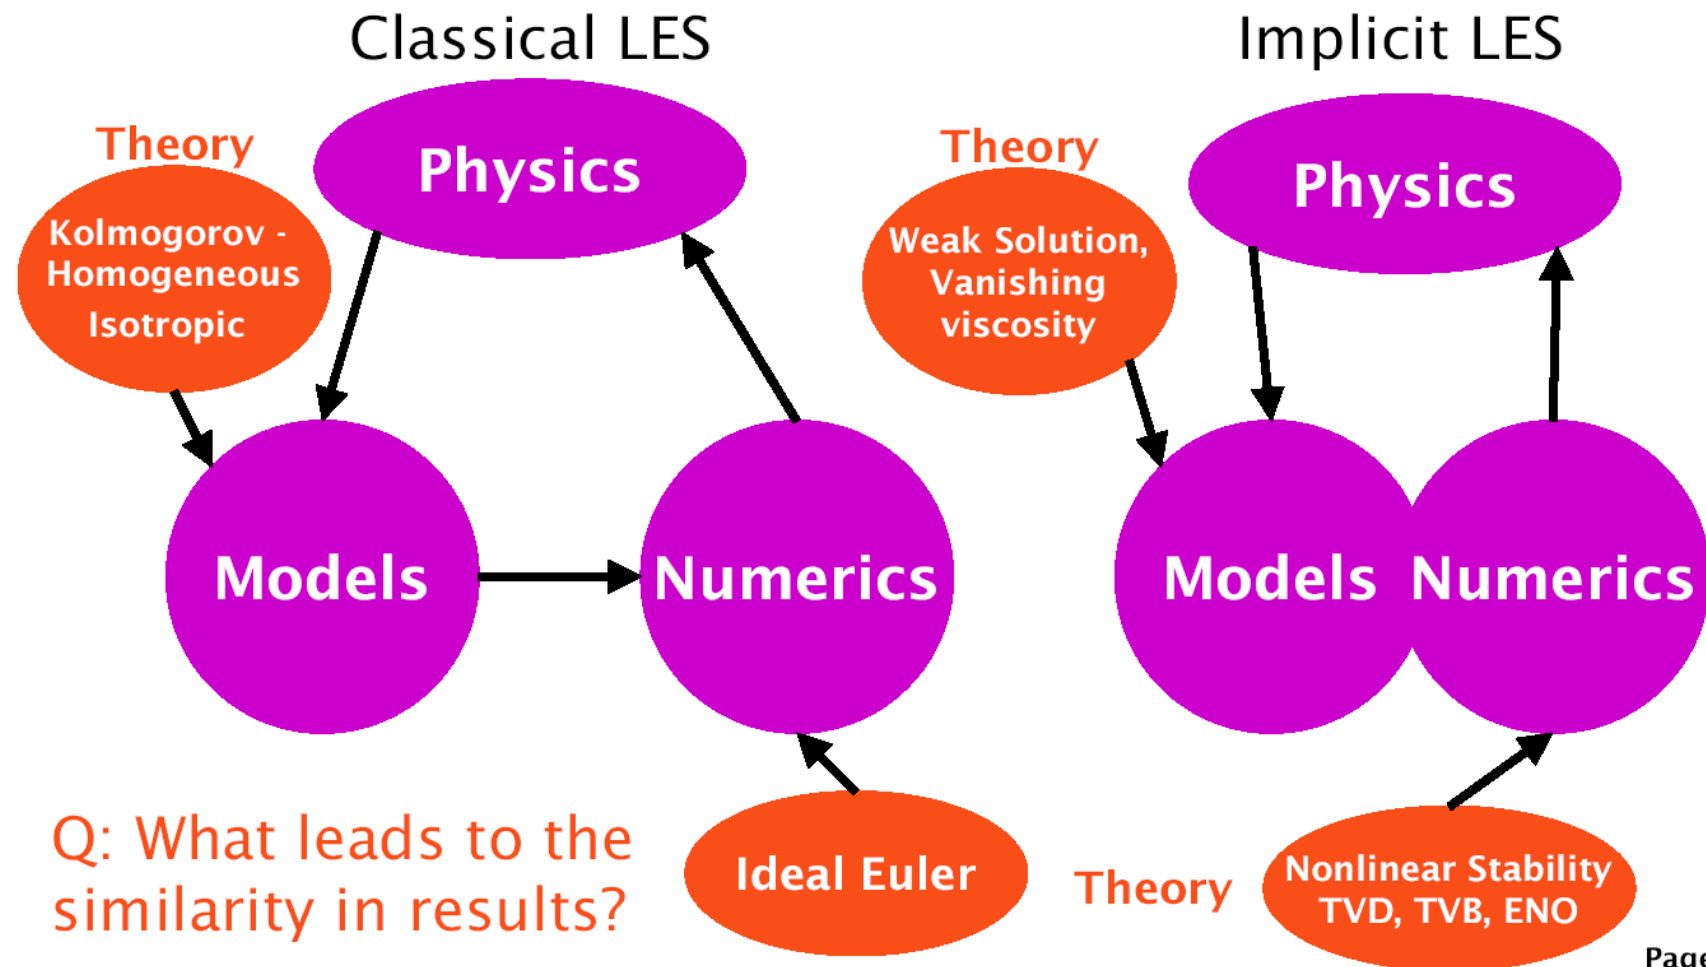

# Energy cascade - Reynolds-Averaged Navier-Stokes (RANS)

# Energy cascade in Large Eddy Simulation

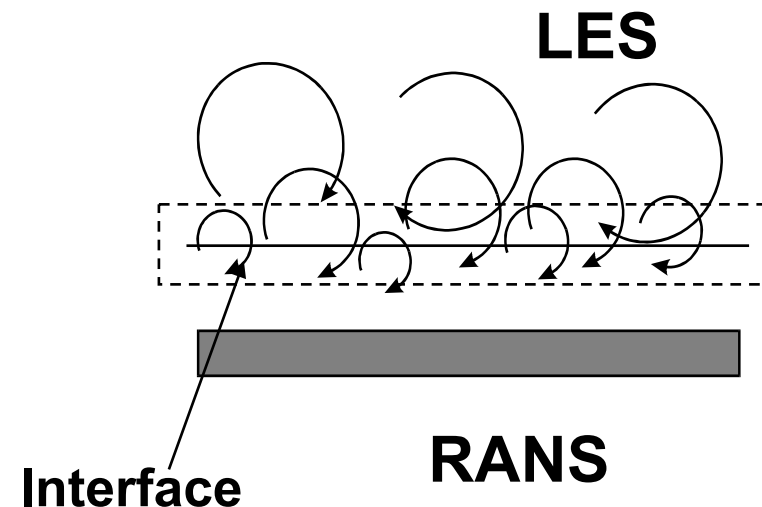

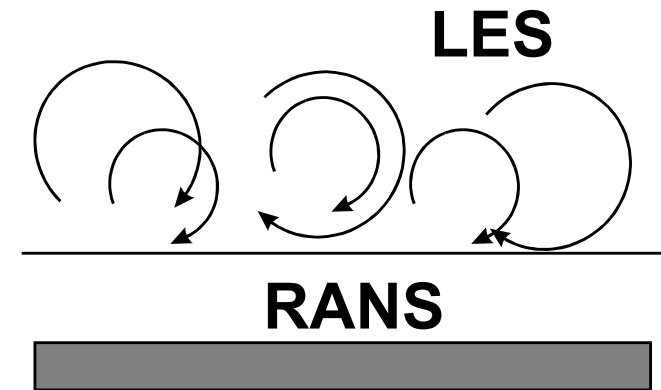

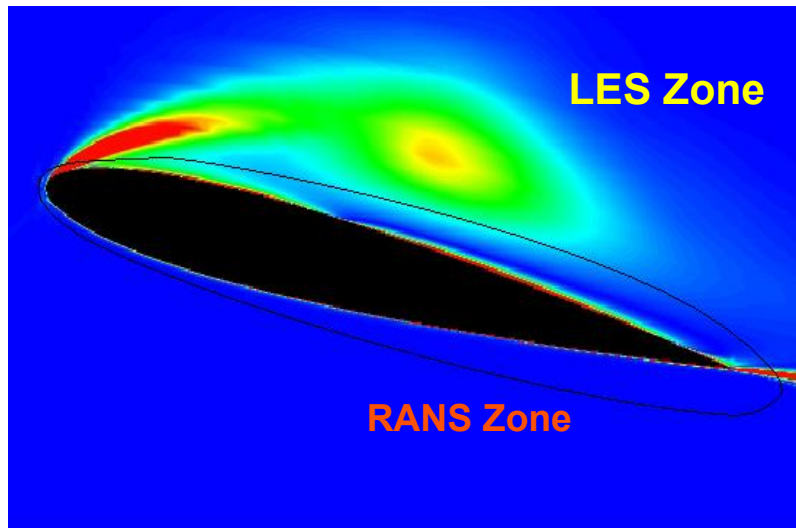

# Classical and Implicit LES

# Implicit & Classical Large Eddy Simulation (LES) and Detached Eddy Simulation (DES)

- ❑ Large Eddy Simulation
  - Implicit LES
  - Classical LES
- ❑ Detached Eddy Simulation

# Computational Models – CFD Code *Azure*

- ❑ Compressible Euler equations
- ❑ Incompressible and Compressible Navier-Stokes equations
- ❑ Reynolds Averaged Navier-Stokes equations
- ❑ Implicit Large Eddy Simulation
- ❑ Detached Eddy Simulation
- ❑ *Non-hydrostatic Euler compressible equations*

$$\frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \mathbf{u}) = 0$$

$$\frac{\partial \rho \mathbf{u}}{\partial t} + \nabla (\rho \mathbf{u} \otimes \mathbf{u}) = -\nabla p + \mathbf{div} \mathbf{T}$$

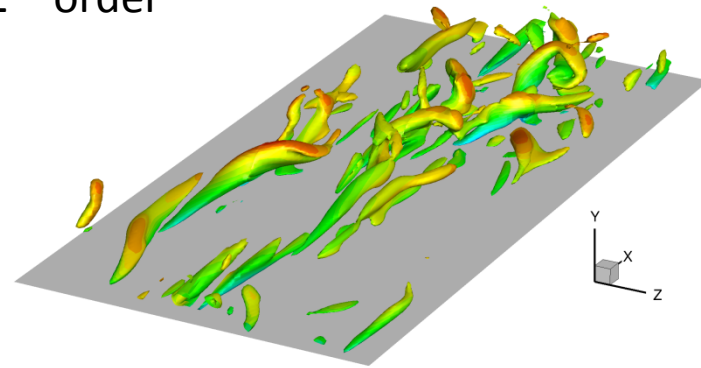

$$\frac{\partial \rho e}{\partial t} + \nabla (\rho \mathbf{u} e) = -p \nabla \cdot \mathbf{u} + \nabla \cdot \mathbf{q}$$

# CFD Code *Azure*

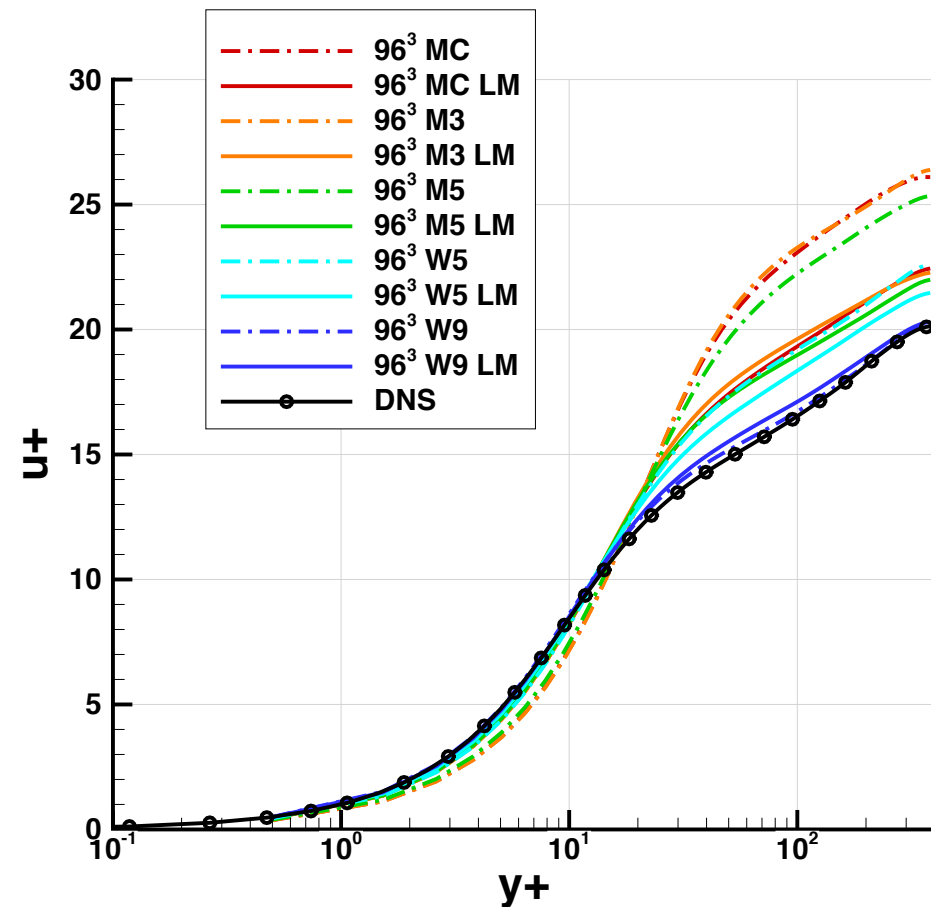

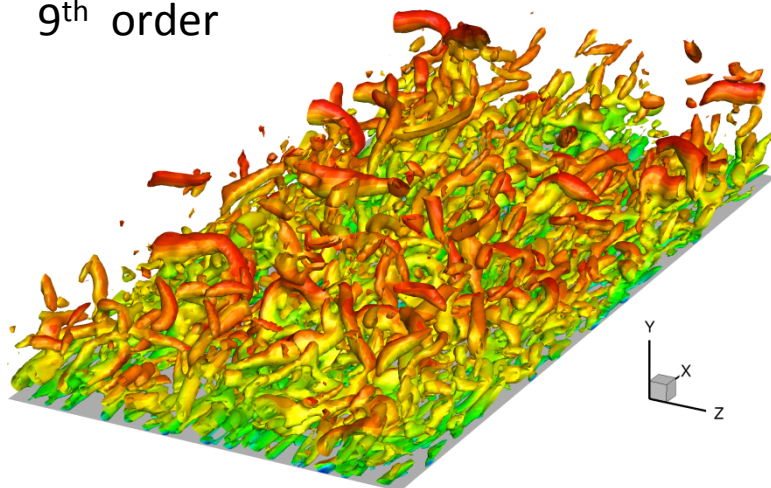

- ❑ Several Riemann solvers (HLLC, Characteristics-based, Rusanov, Roe)
- ❑ Explicit Runge-Kutta time stepping schemes from 1<sup>st</sup> to 4<sup>th</sup> order of accuracy for unsteady flow problems
- ❑ Implicit time stepping LU-SGS based on 1<sup>st</sup>-order approximate Jacobians used with local-time stepping for convergence acceleration to steady state solutions
- ❑ **RANS** with Spalart-Allmaras, K- $\omega$  (SST) turbulence models
- ❑ **Detached Eddy Simulation (DES)** or **hybrid RANS/LES** with Spalart-Allmaras and K- $\omega$  turbulence Models
- ❑ **Implicit Large Eddy Simulation (ILES)**
- ❑ RANS transport variables can be discretised in the same manner as the mean flow equations

# Near wall turbulence

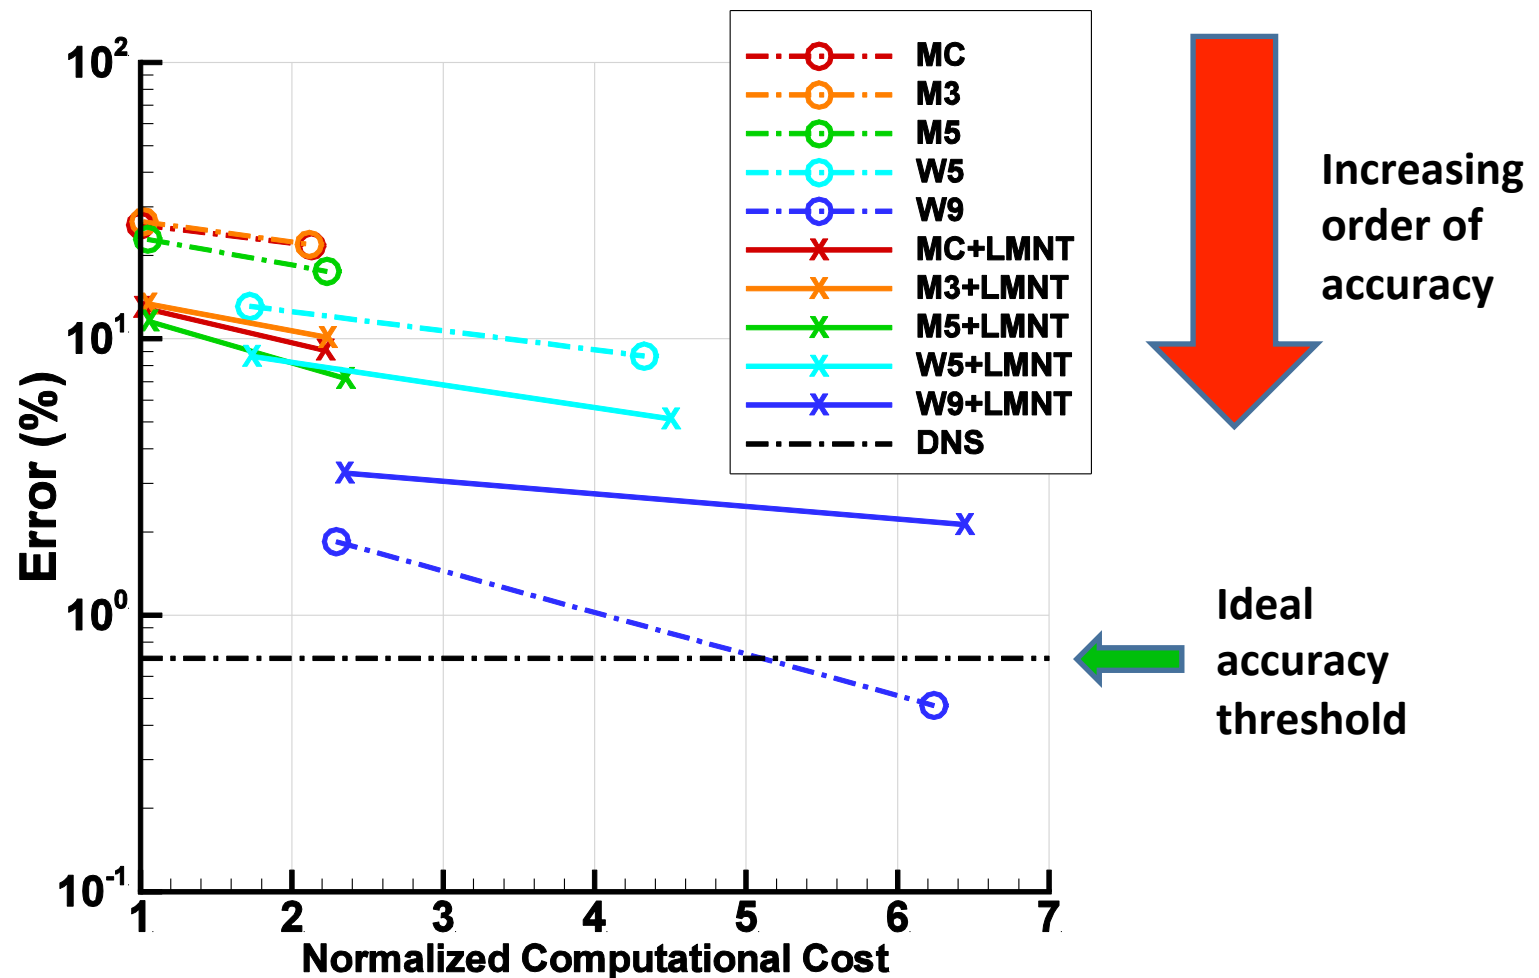

2<sup>nd</sup> order

9<sup>th</sup> order

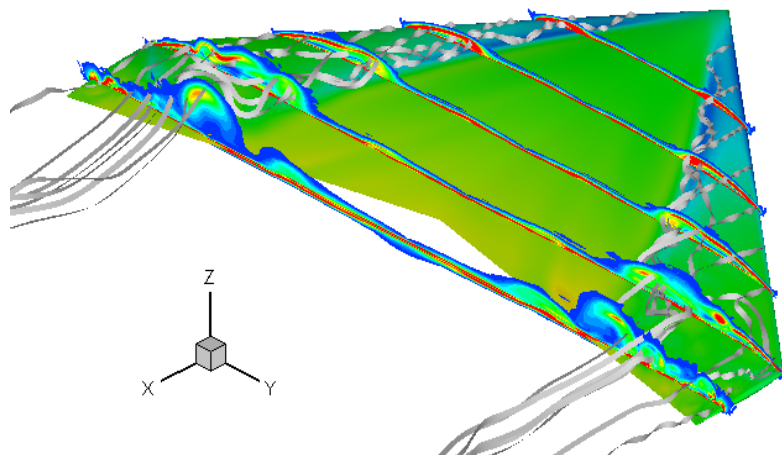

# Accuracy vs computational cost

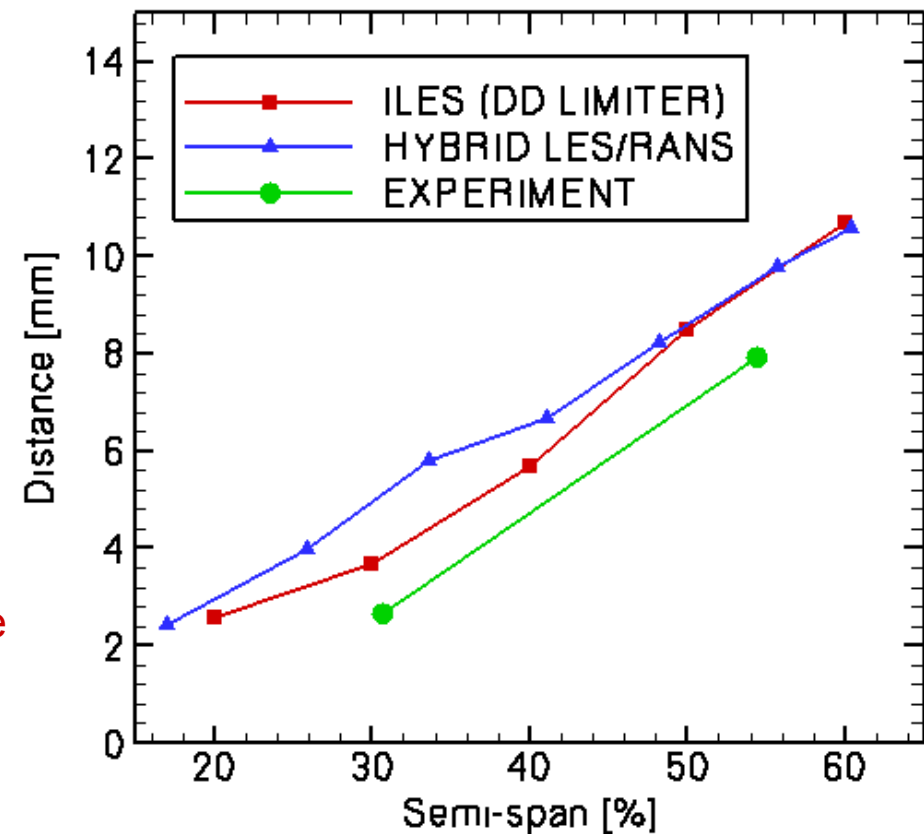

# Separated flows – Swept wings

$Re=2 \times 10^5, M=0.03$

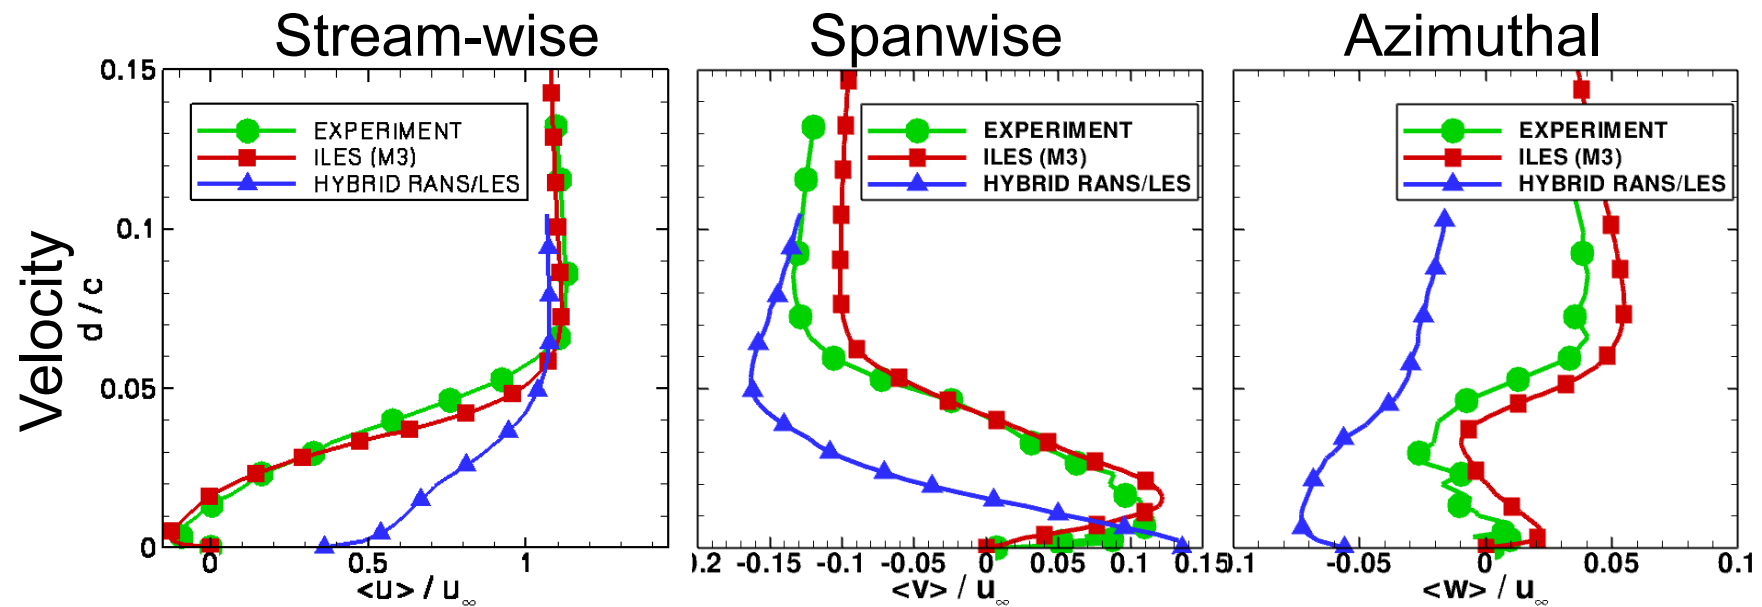

Instantaneous streamlines, vorticity and pressure

## Clearance of the vortex core

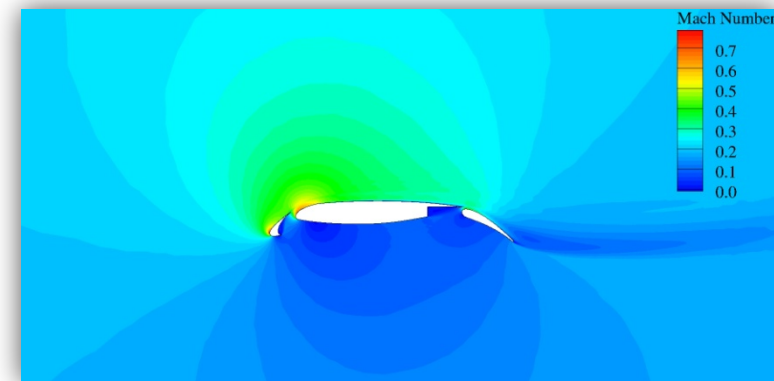

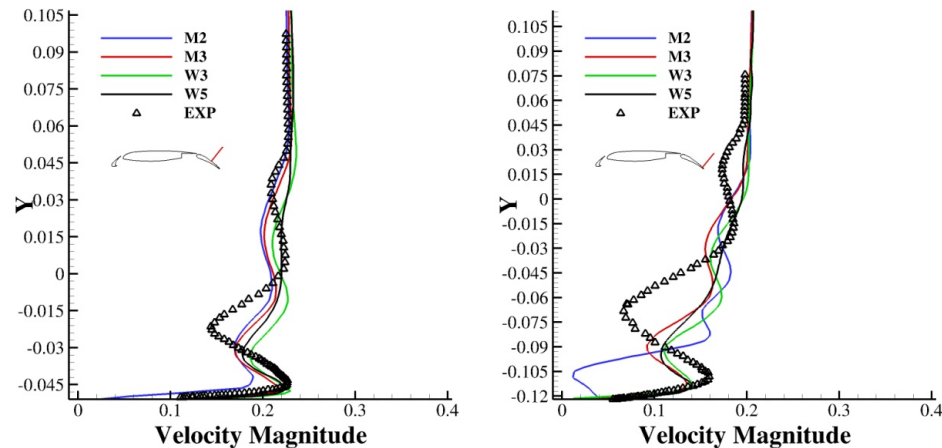

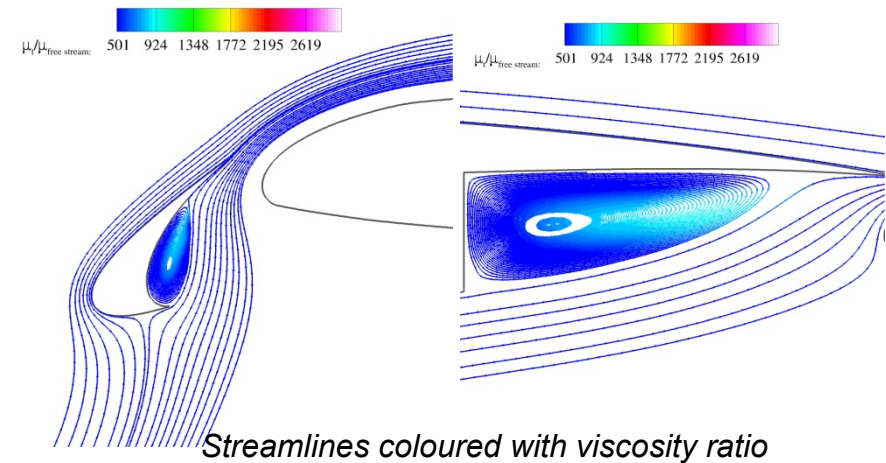

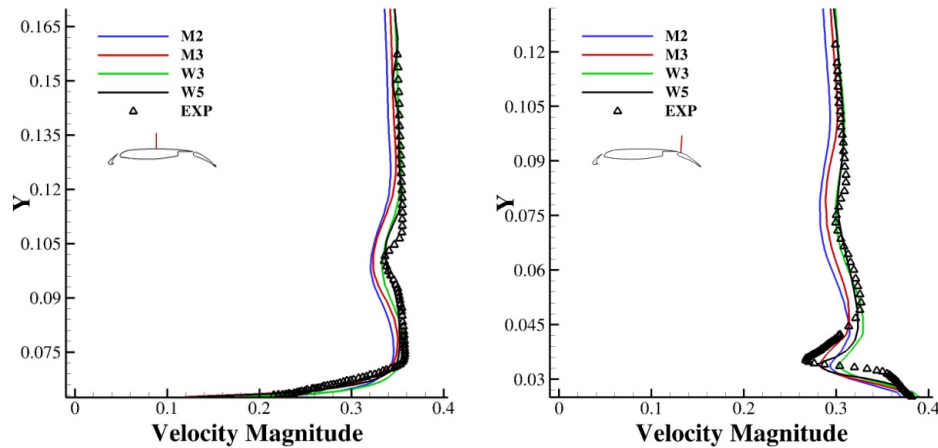

# ILES vs hybrid RANS/LES

90% half-span, 50% local chord

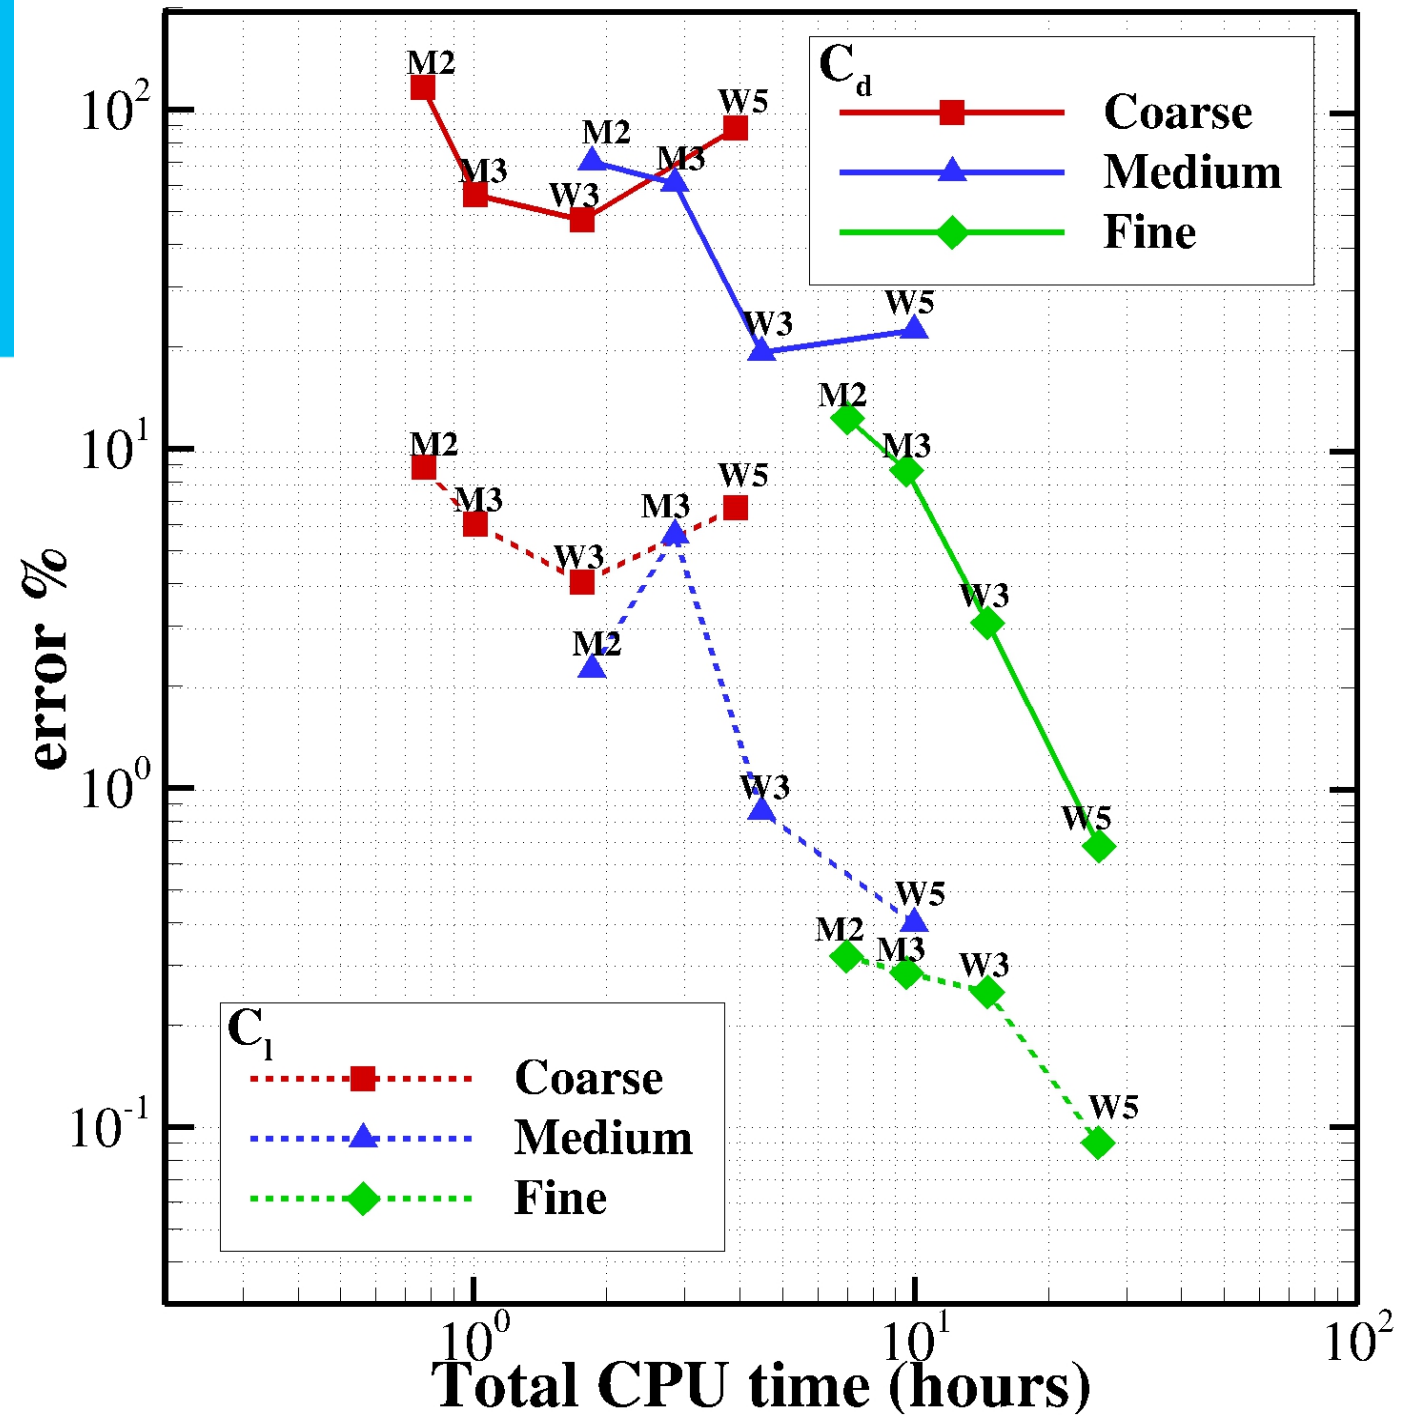

# Subsonic Flows

## MDA 30P-30N

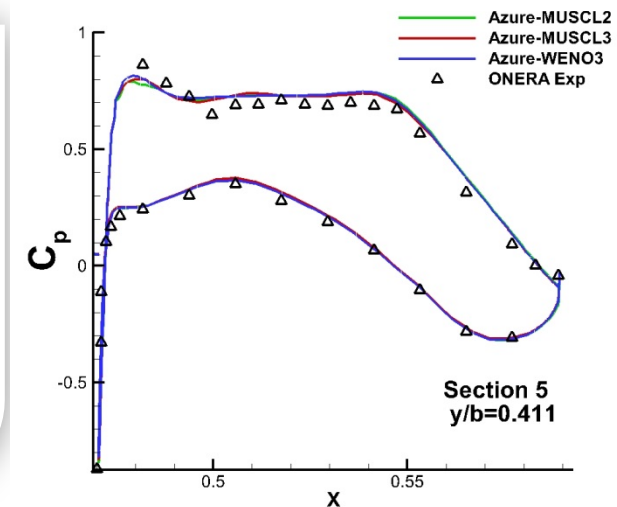

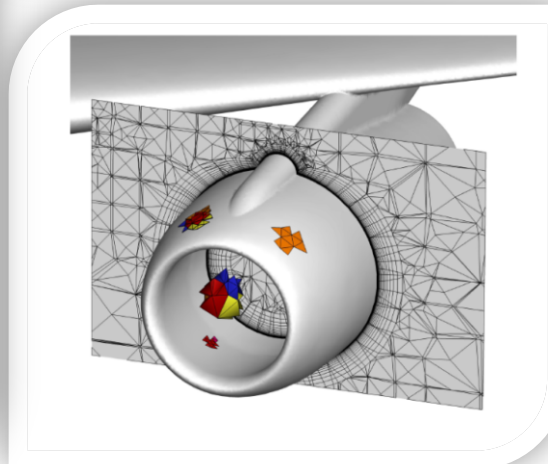

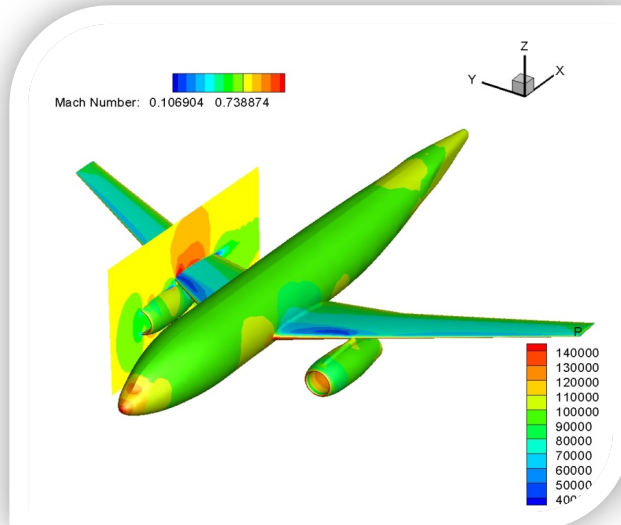

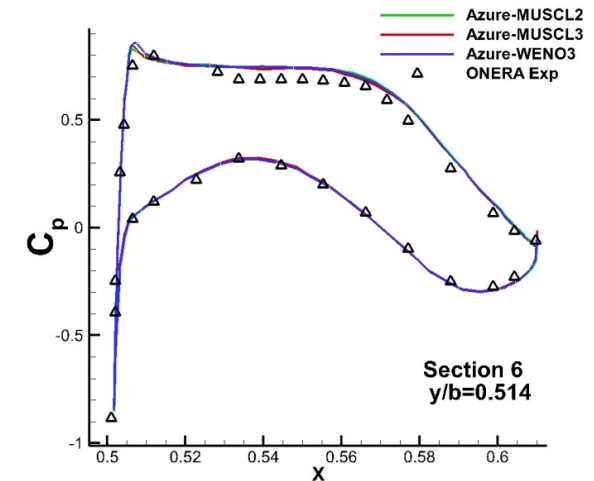

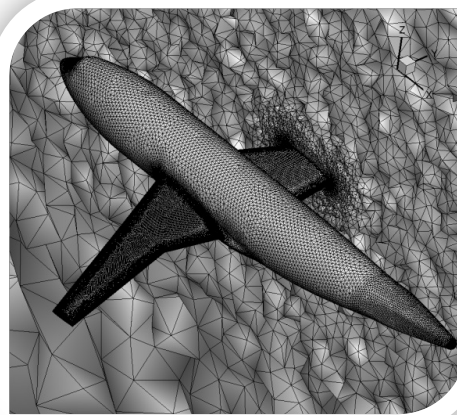

# Computational efficiency vs error reduction

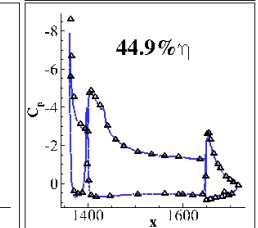

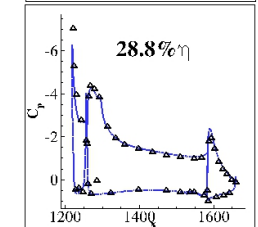

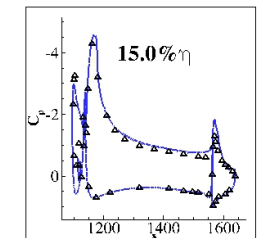

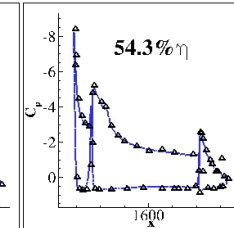

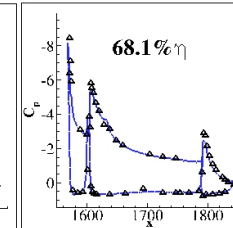

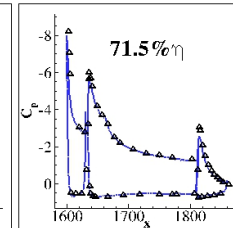

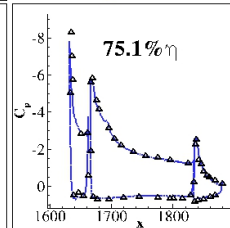

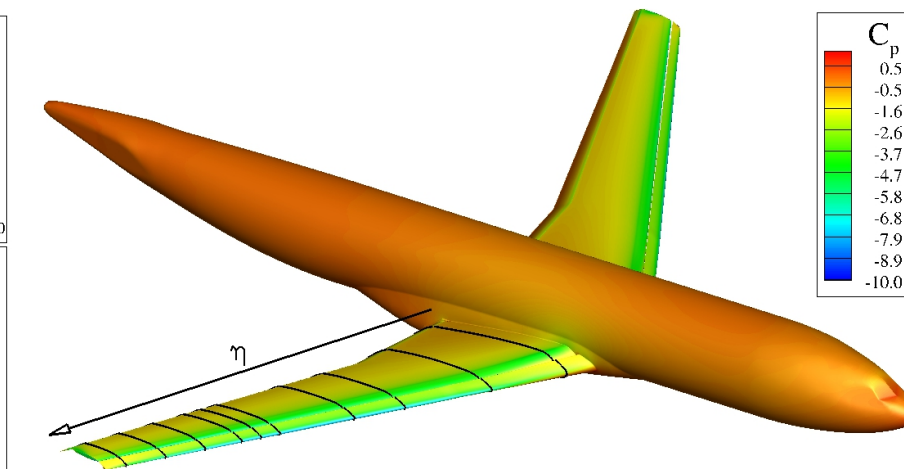

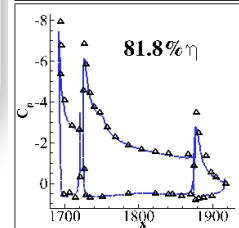

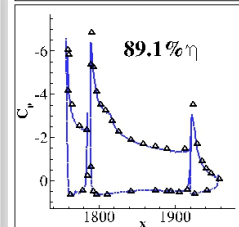

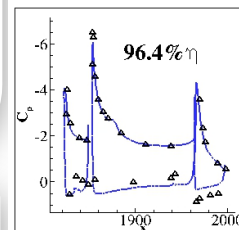

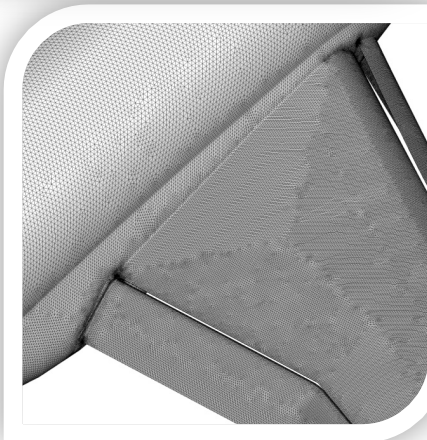

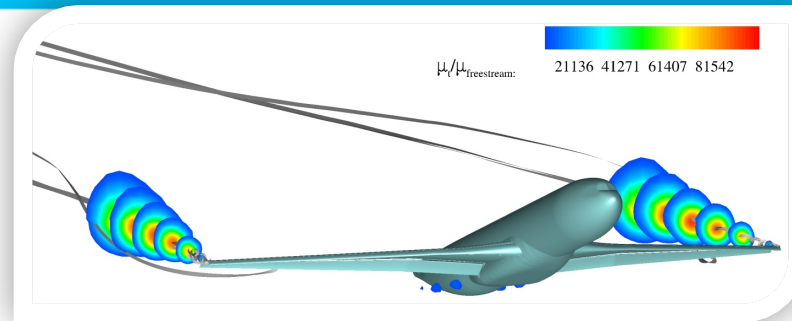

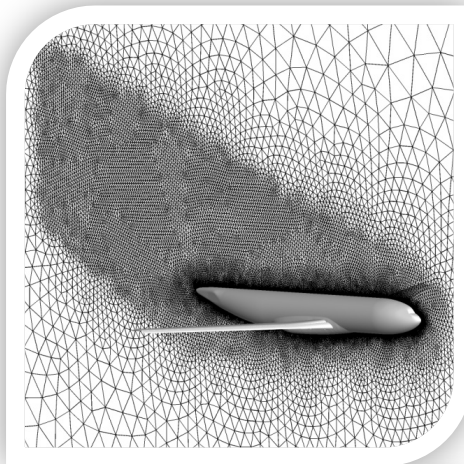

# Transonic DLR F6 aircraft

## Azure CFD code

Convergence achieved  
in less than 17 hours for  
a WENO 3<sup>rd</sup>-order  
scheme, on one node of  
16 CPUs, 5M grid points

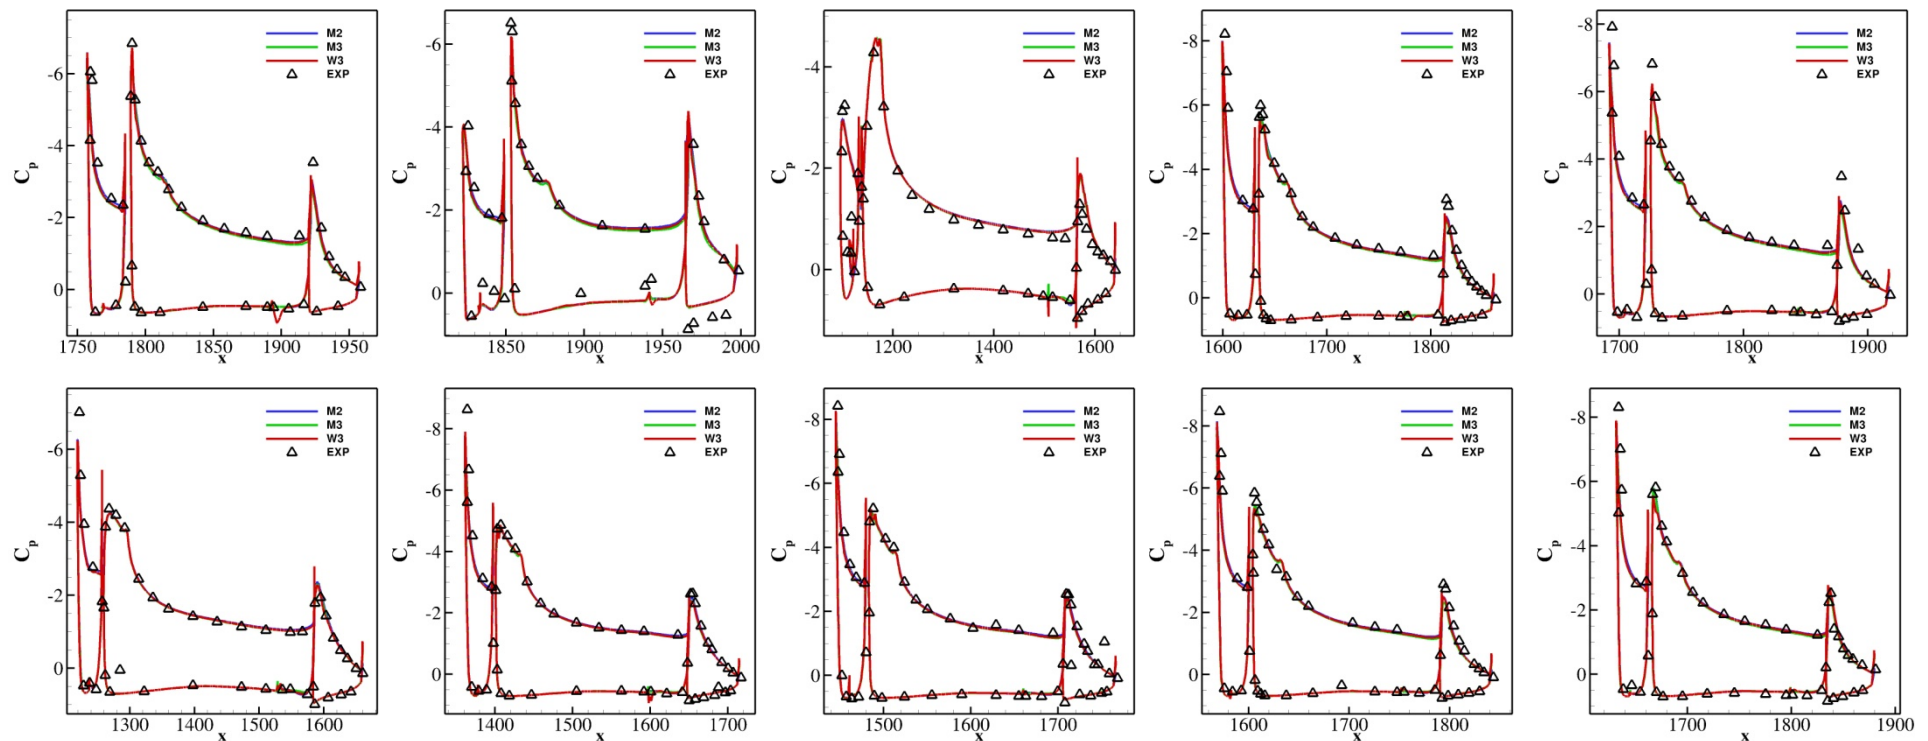

# DLR F11 aircraft – *Azure* CFD code

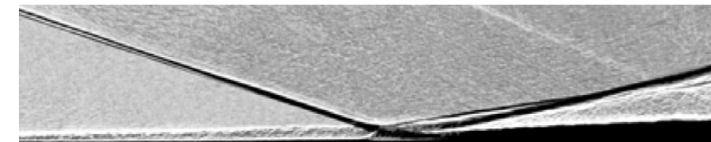

# Pressure coefficient – comparison of methods

Full aircraft DLR-F11 high-lift configurations  
with MUSCL 2<sup>nd</sup>, 3<sup>rd</sup> and WENO 3<sup>rd</sup> order schemes

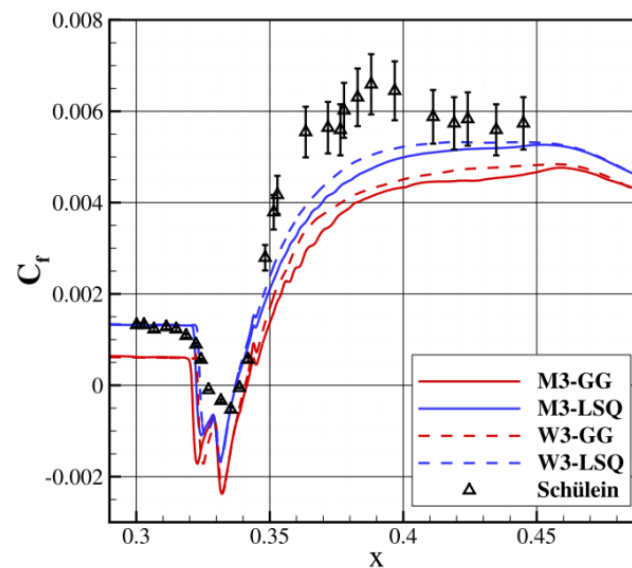

# Shock wave/boundary layer interaction

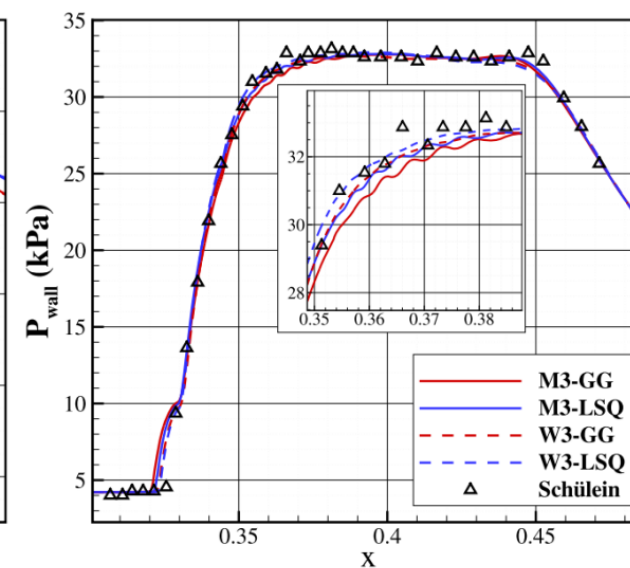

- Qualitative results showing the computed density for the WENO 3<sup>rd</sup> order scheme illustrating the shock structure compared with the shadowgraph from the experiment.
- Comparison of gradient reconstruction Green Gauss (GG) and least-square (LSQ) with the experimental data

(a) Experimental shadowgraph

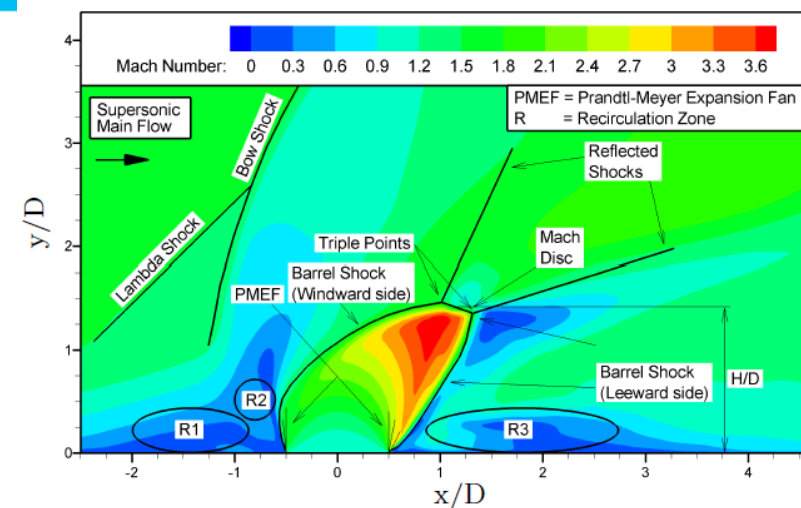

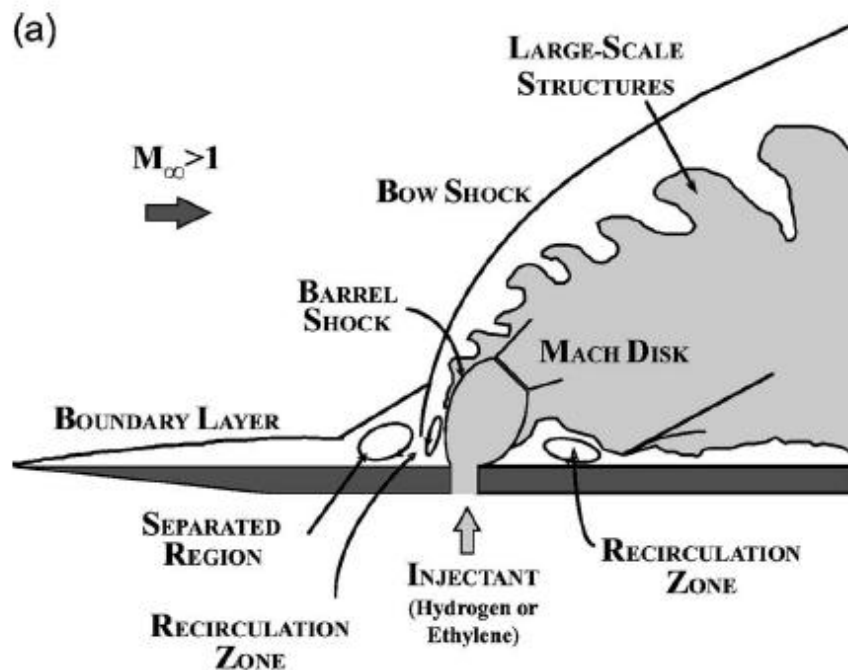

Skin friction coefficient ( $C_f$ )

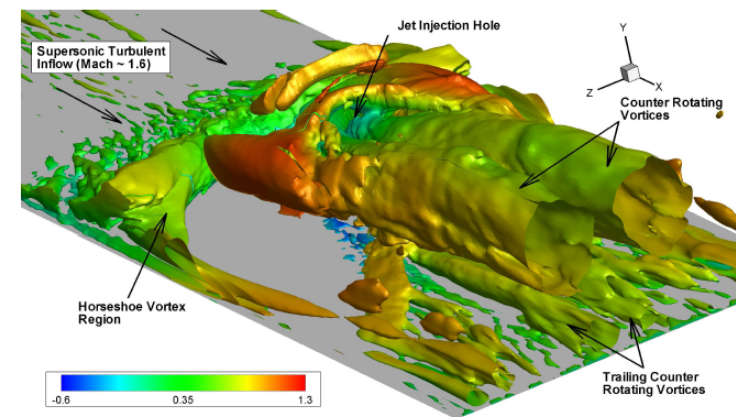

Wall pressure ( $P_{wall}$ )

# Sonic Transverse Jet in a Supersonic Cross-flow (JISC)

JISC was studied experimentally to understand the effects of the injection of a sonic circular jet on a supersonic cross-flow transversely.

(a) 2D flow features on mid plane ( $z/D=0$ )

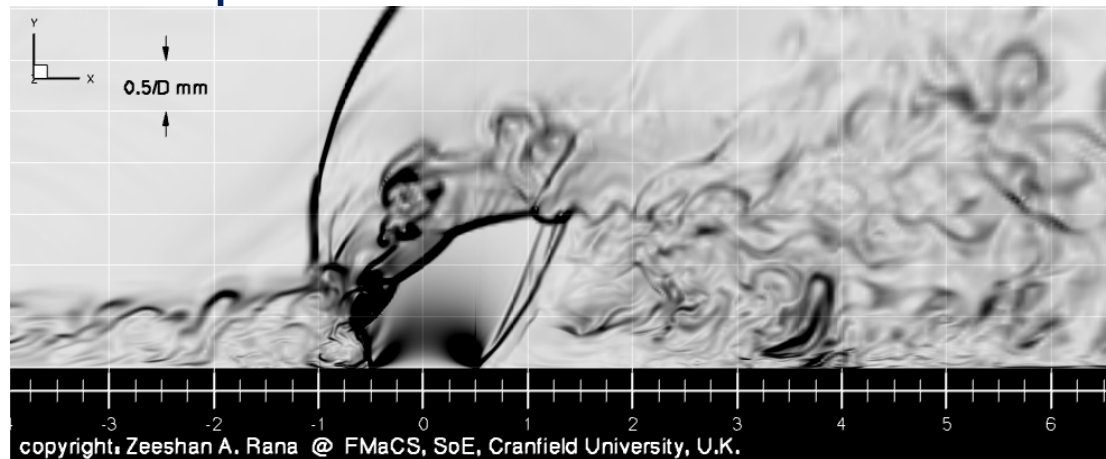

(b) 3D flow features; Q criterion Iso-Surfaces

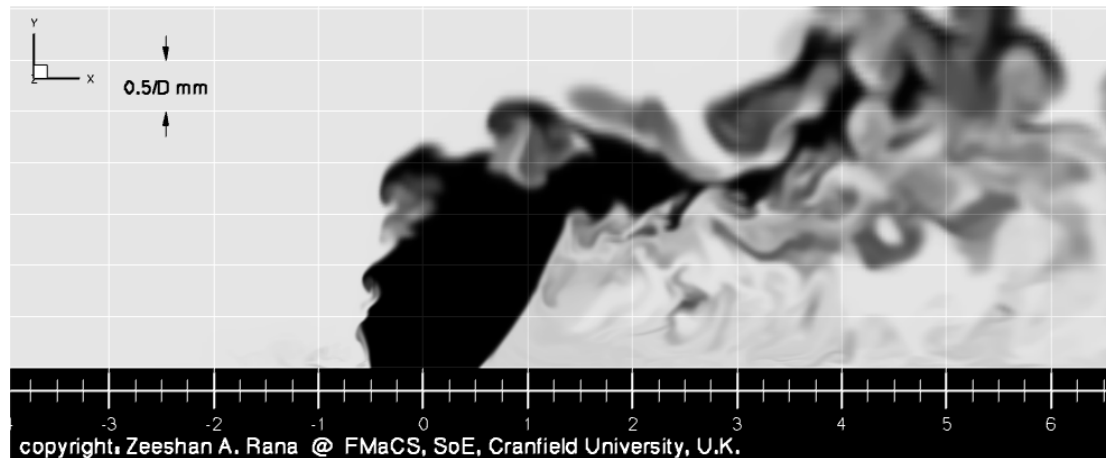

## Results – Mach 1.6 JISC Experiment:

- Flow animations:

(a) Density Gradient,

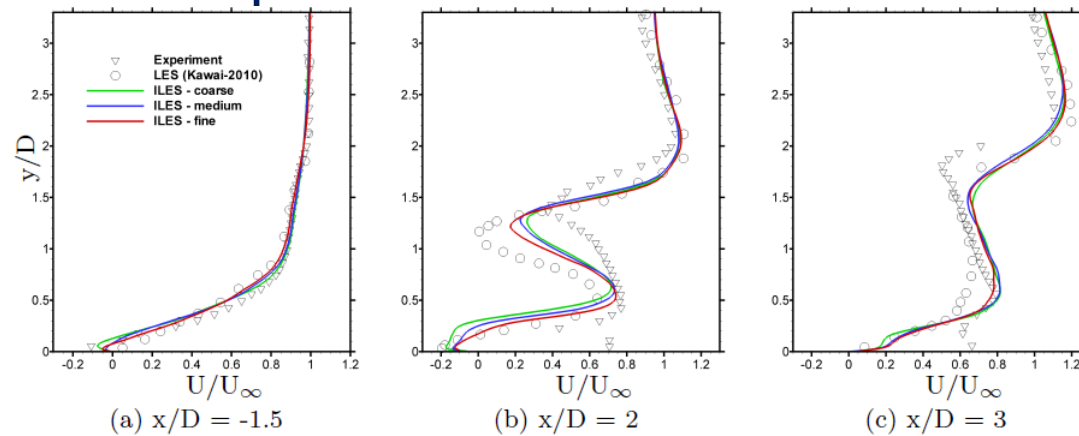

(b) Passive Scalar

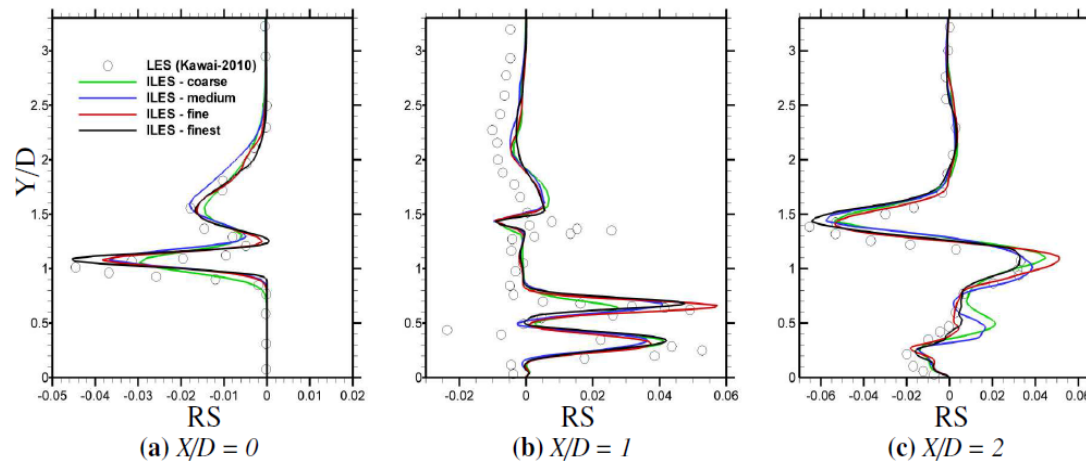

## Results – Mach 1.6 JISC Experiment:

Streamwise  
Velocity Profile  
Comparison at  
mid-plane ( $z=0$ )

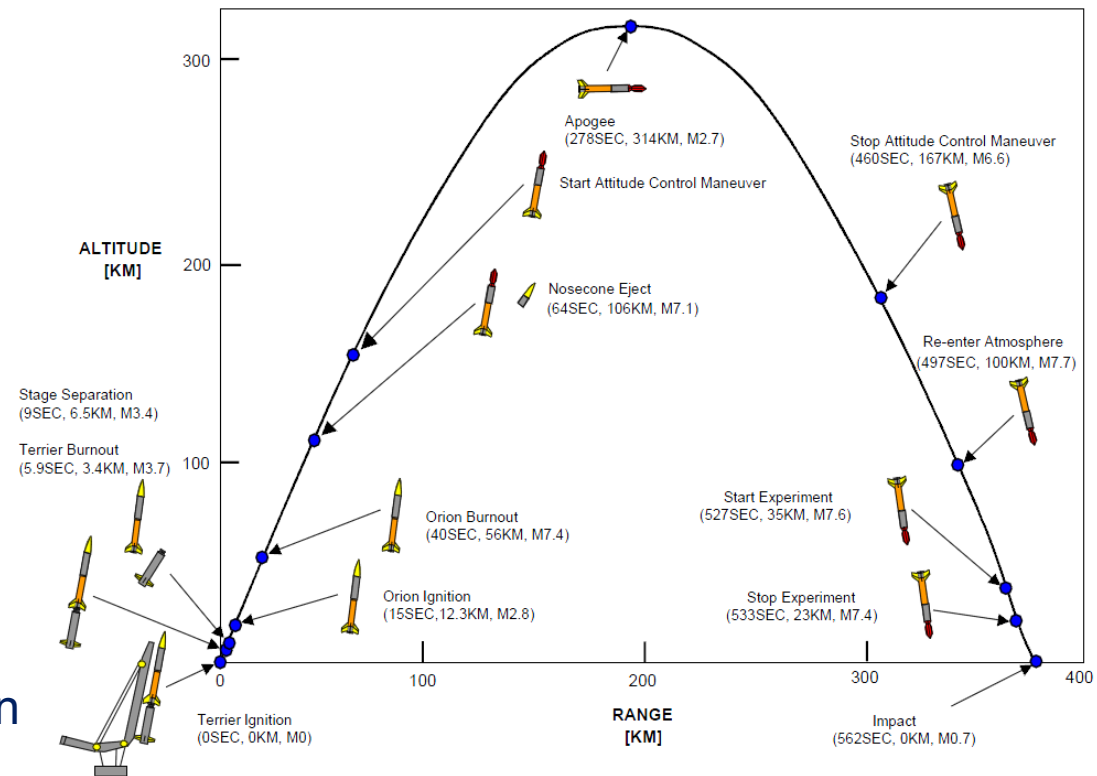

Turbulent Kinetic  
Energy Profile  
Comparison at  
mid-plane ( $z=0$ )

# HyShot-II

## HyShot-II Scramjet:

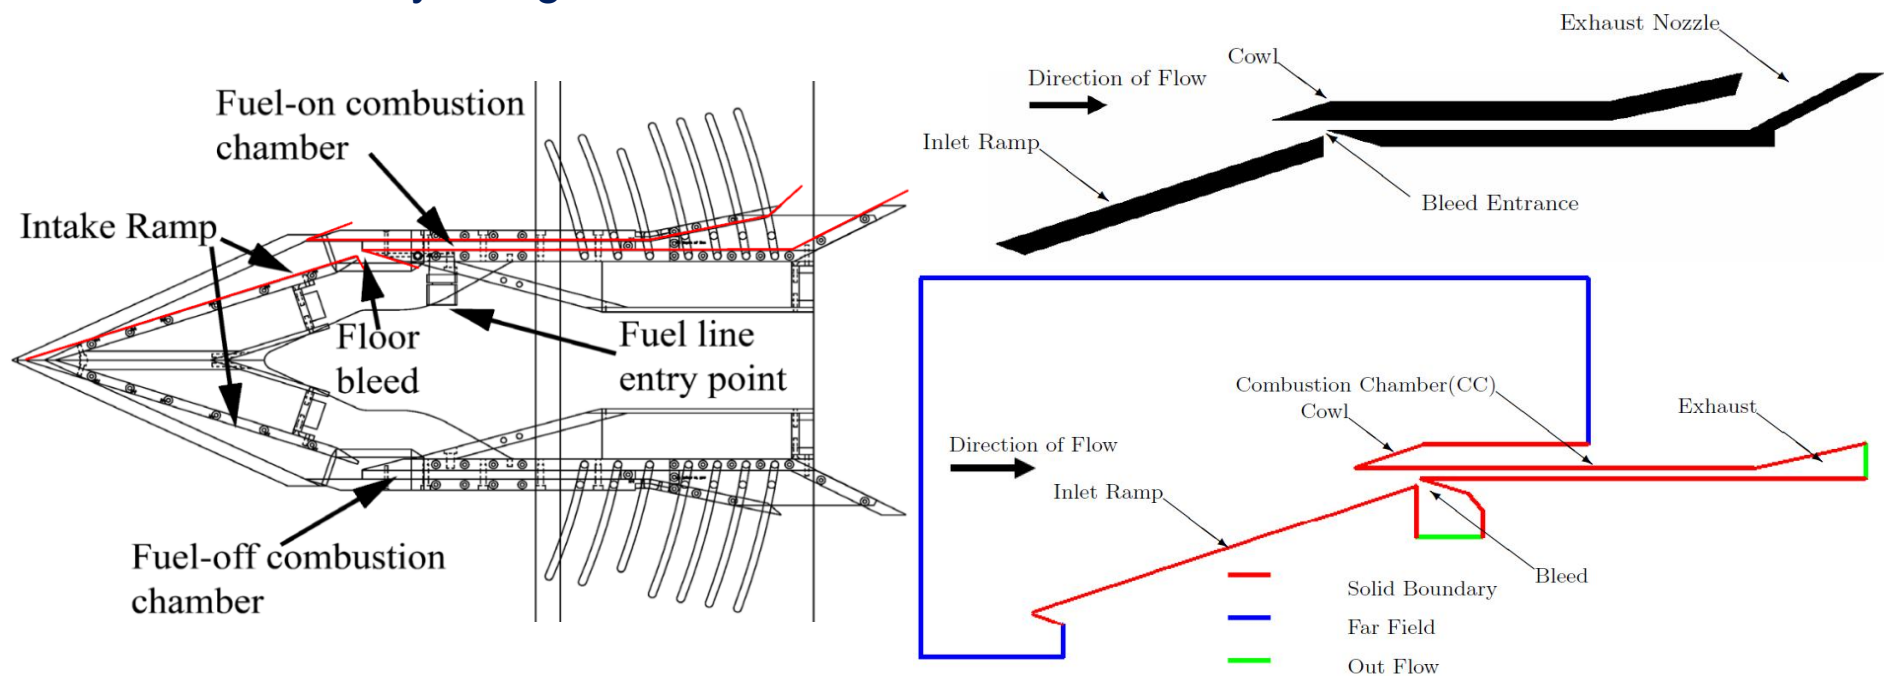

- Successful test flight – 30<sup>th</sup> July 2002
- Achieved Supersonic Combustion (SC) at Mach 7.6 at altitude of between 35 km and 23 km.
- Fuel - Gaseous Hydrogen
- Highly parabolic trajectory (near Vertical decent) to obtain correlations over a range of ambient pressures.

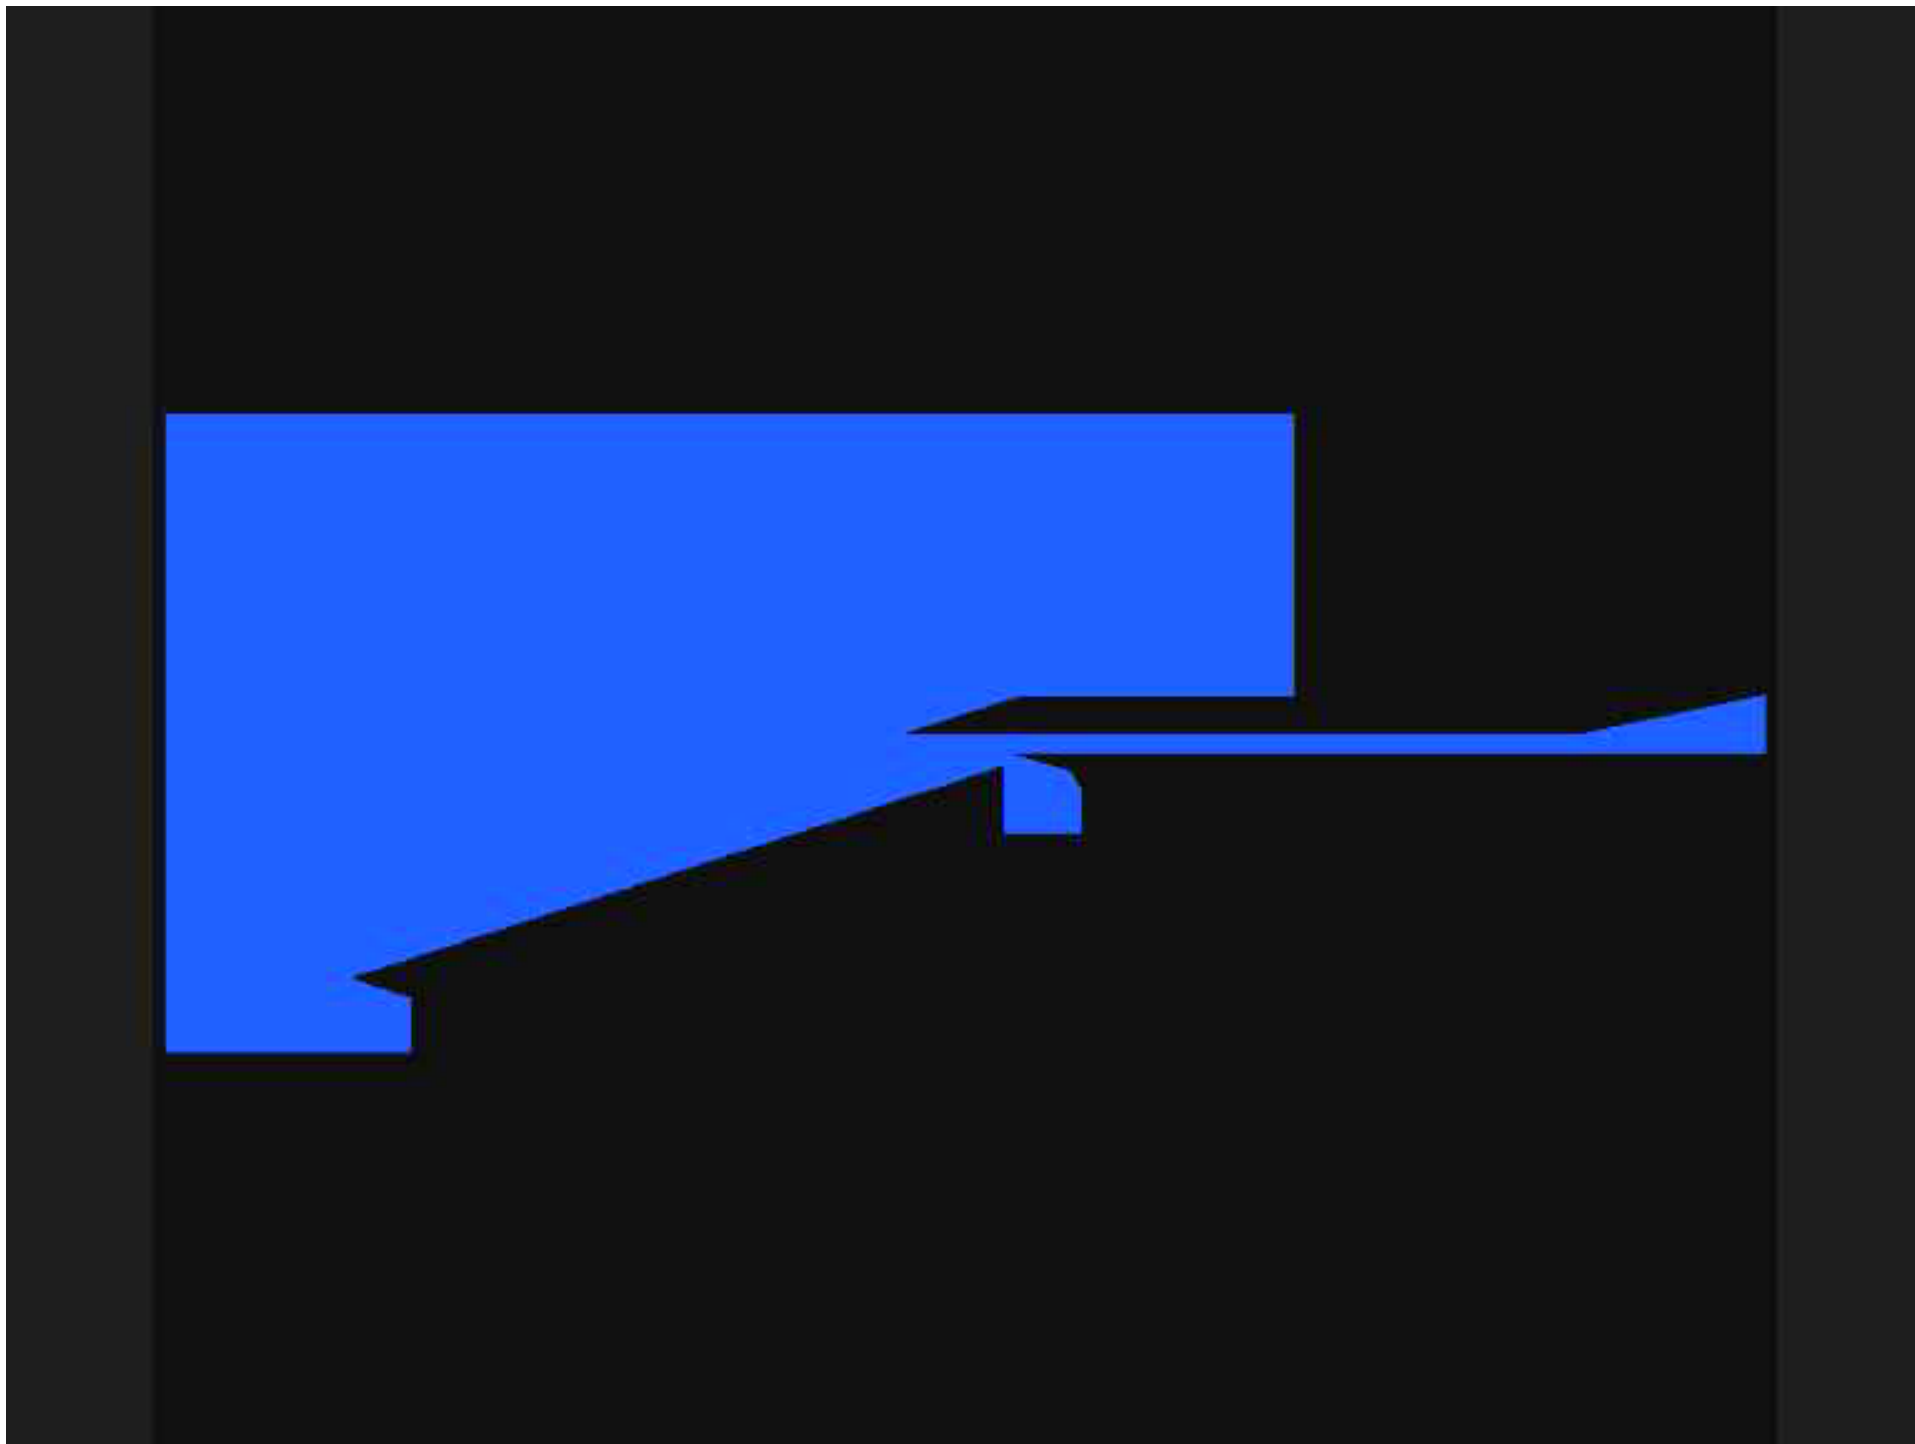

# HyShot-II

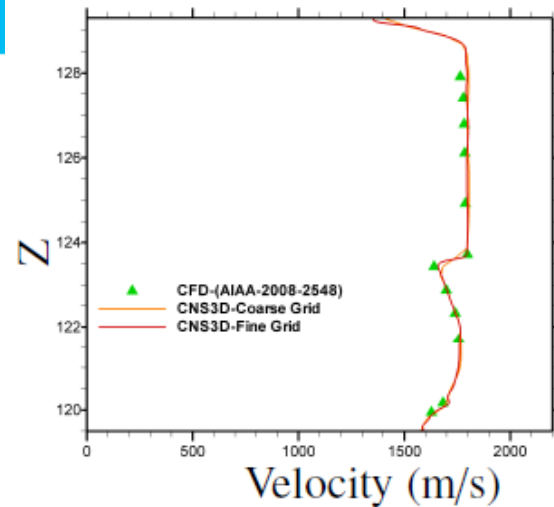

## Results – Analysis of the HyShot-II Scramjet:

- Pressure measurements - the primary means for obtaining the correlation
- Combustion and non-combustion investigations on the geometry are carried out at DLR, Germany using HEG and CFD.

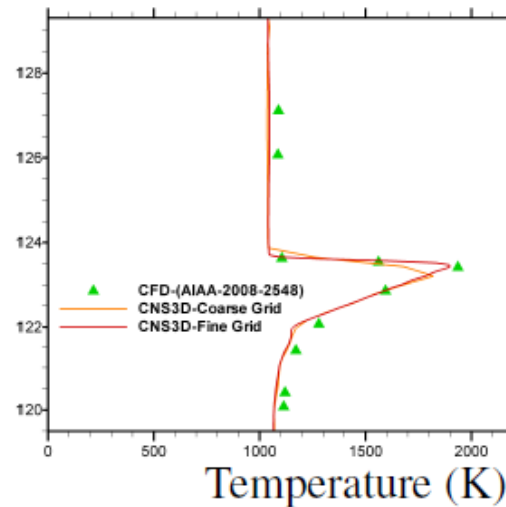

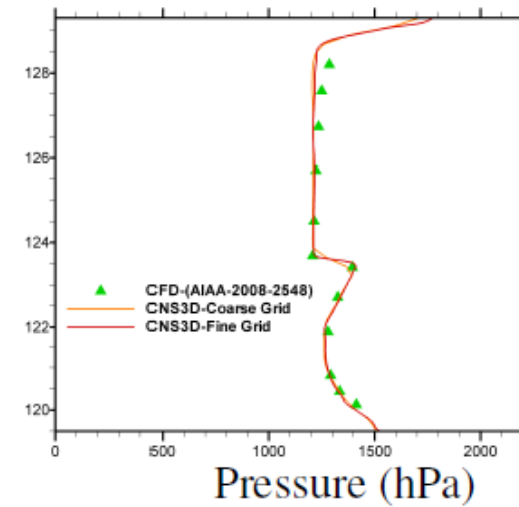

# HyShot-II

(c)

# Launcher Aerodynamics

- Ariane nozzles experience high side loadings due to vortex shedding
- Can cause serious control issues and
- Limit the development of combustion chambers as longer nozzles cannot be employed

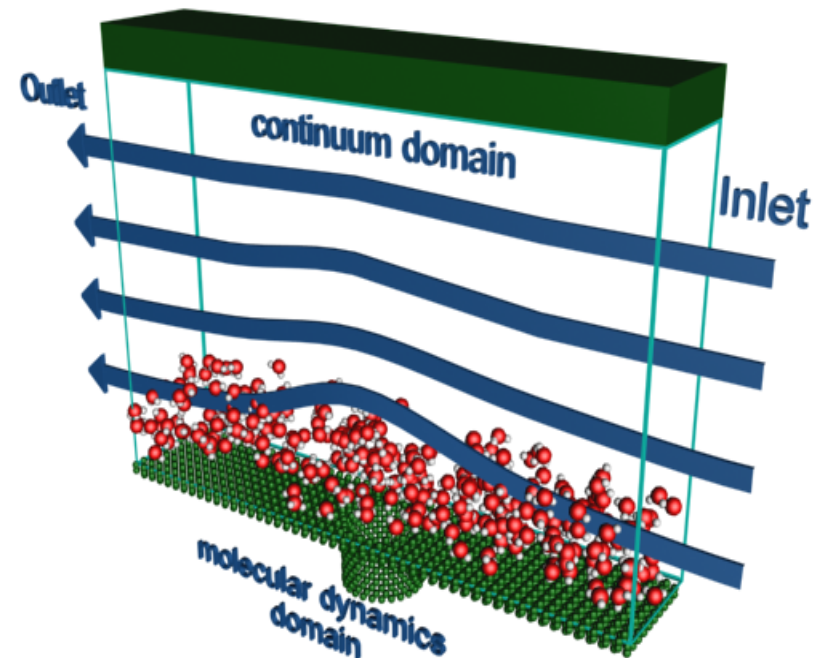

# UAV flying formation

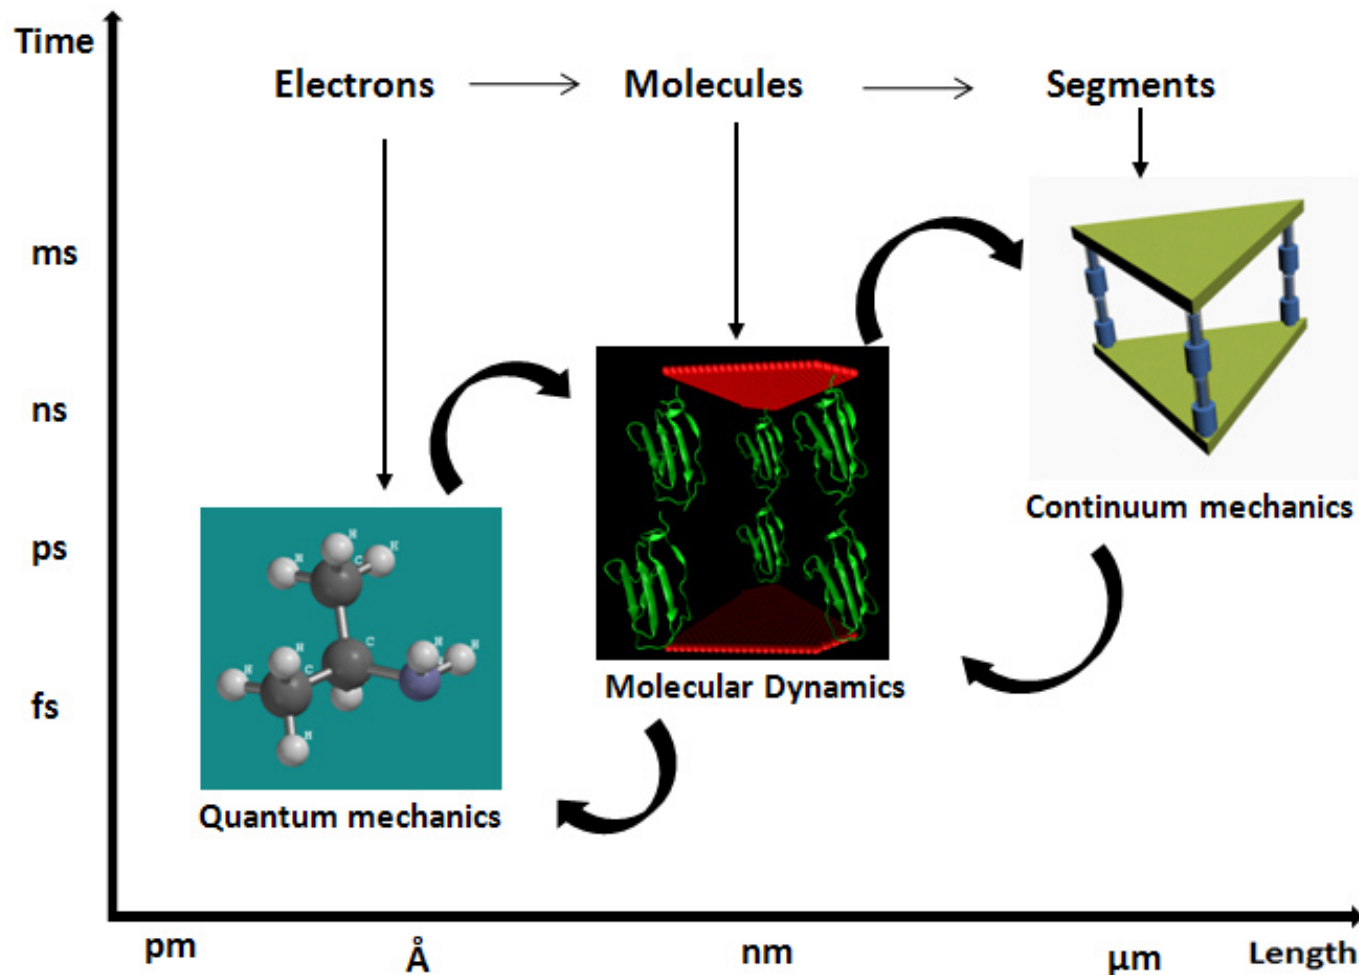

# From Macro to Nano Scale

- Several new applications and design concepts require understanding of fluid/material phenomena and interactions at micro and nano scale.
- This motivates the design of multi-scale methods
- Multi-scale modelling and simulations can also be used in support of the development of simpler engineering models.

**Example of coupling flow, near-wall molecular transport, and solid material**

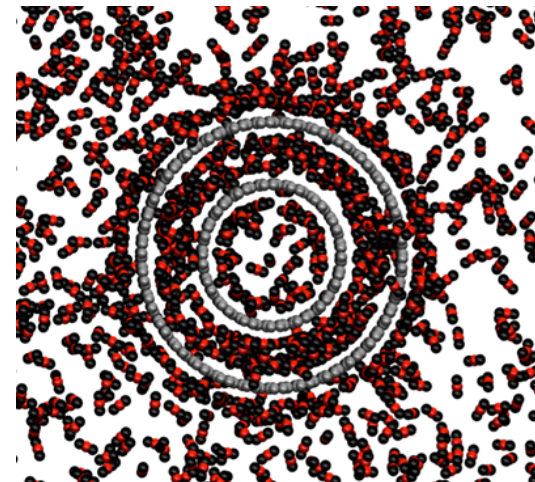

# Molecular and Multi-Scale methods

# Molecular Dynamics

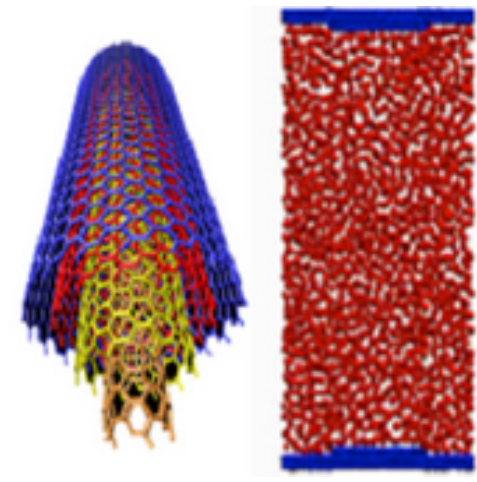

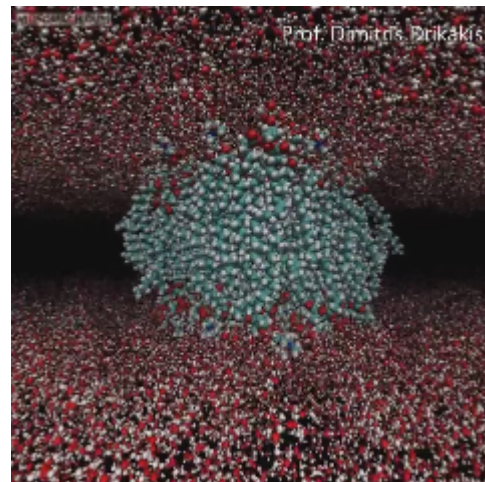

## Effective for studying confined fluids

- Investigate interface effects from first principles
- Level of detail beyond experimental possibilities

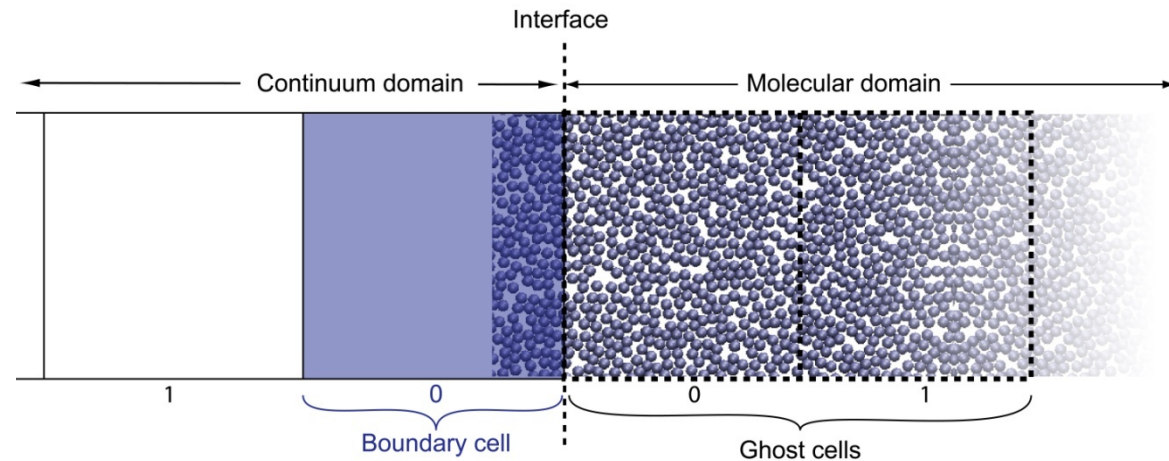

## Challenges

- Difficult to accurately model complex physical systems
- Complications in extracting macroscopic properties from phase space trajectories
- Computational expense

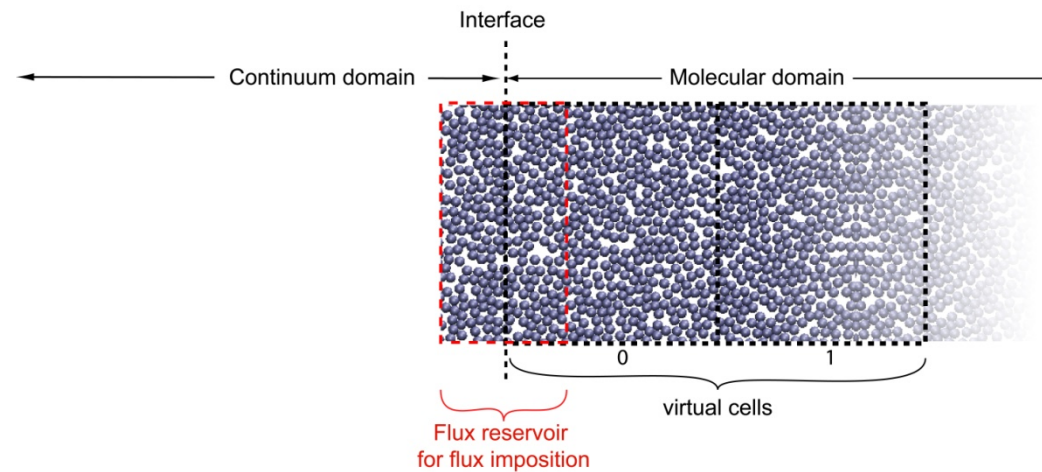

# Hybrid solution interface

**Continuum  
perspective**

**Molecular  
perspective**

# Point-wise coupling

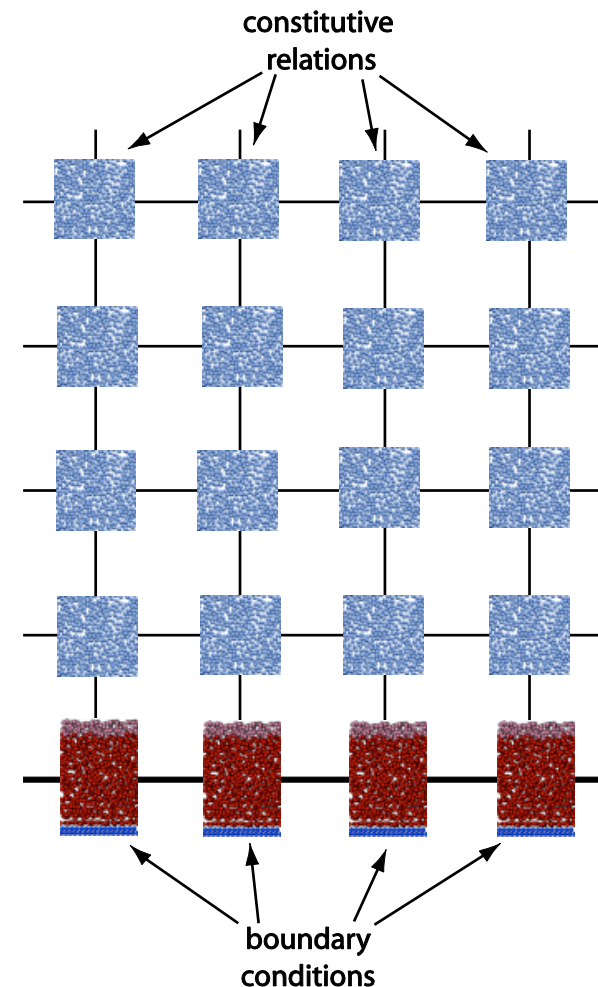

- Continuum covers the entire domain
- MD solver is used as a local refinement to replace analytical or empirical models
- Two types of relations:

## Constitutive relations:

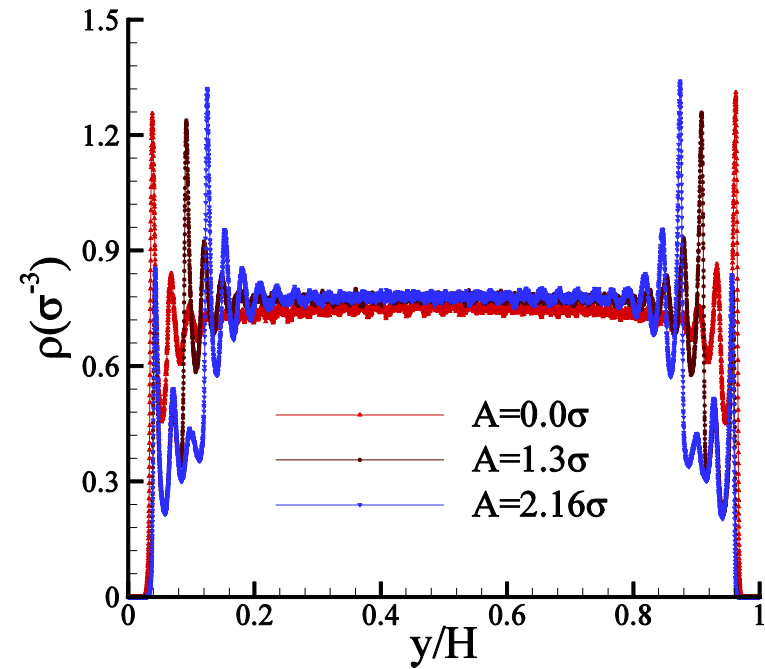

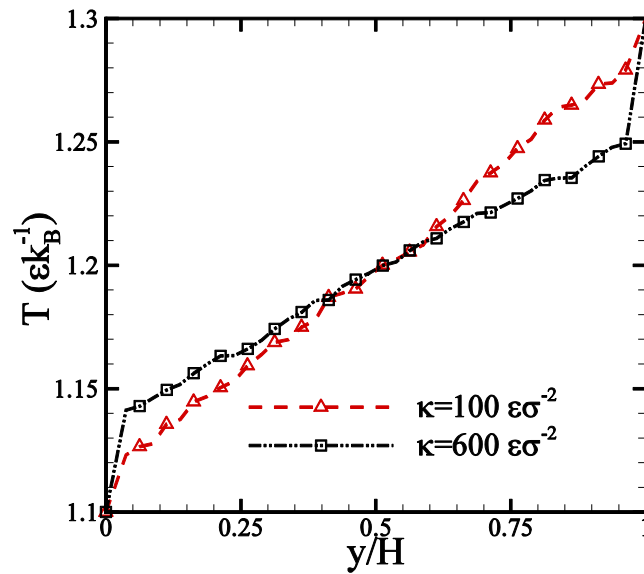

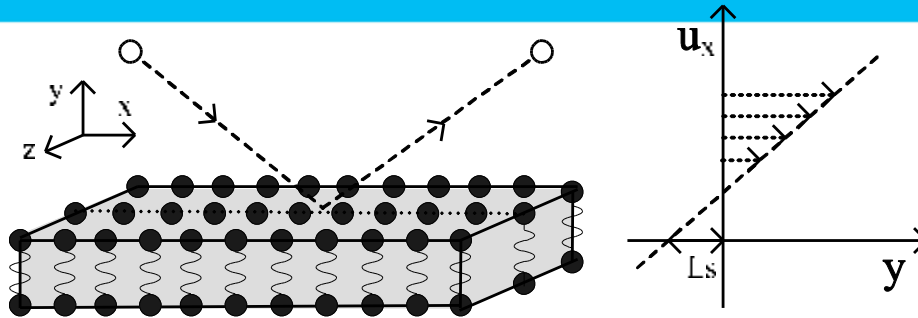

- Compute equations of state, e.g.,  $p=p(r, \mathbf{c}, T)$
- Compute transport coefficients, e.g., viscosity, diffusion coefficient, heat conductivity

## Boundary conditions:

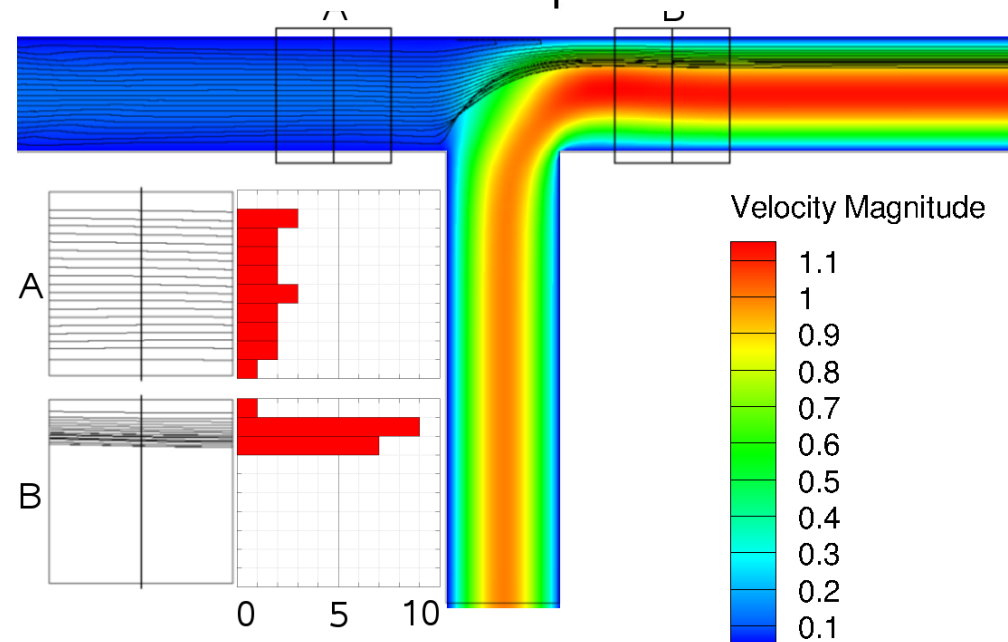

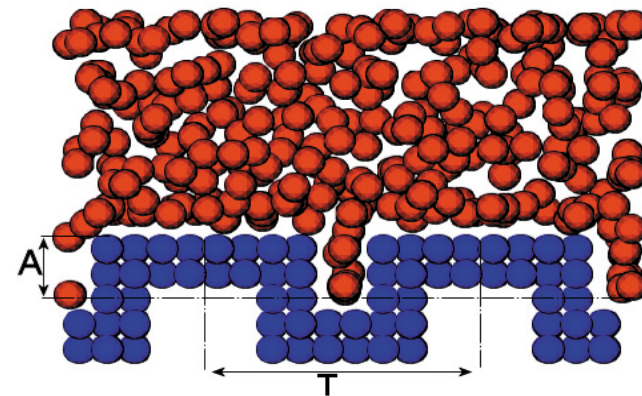

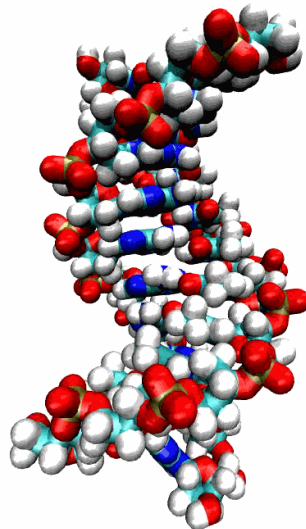

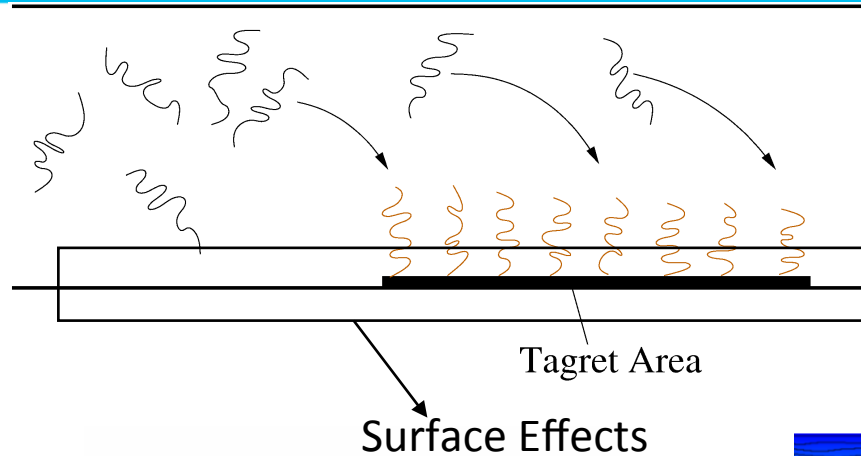

- Tangential stress  $t_t = t_t(r, \mathbf{c}, T, u)$ ,
- Heat flux,  $q=q(r, \mathbf{c}, T, u)$
- slip velocity,  $v_s = v_s(r, \mathbf{c}, T, u)$ ,

# Modelling surface effects

# DNA transport in micro-fluidics

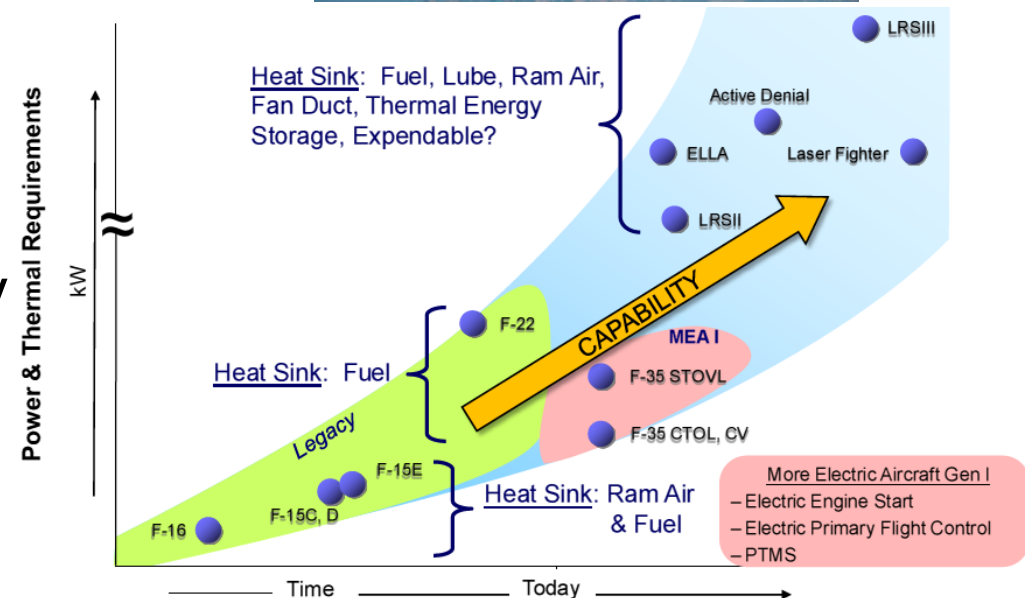

# Thermal Management

## Important problem in avionics

- Heat fluxes of the order of  $10^3 \text{ W/cm}^2$
- Failures during flight
- Limiting factor for additional functionality

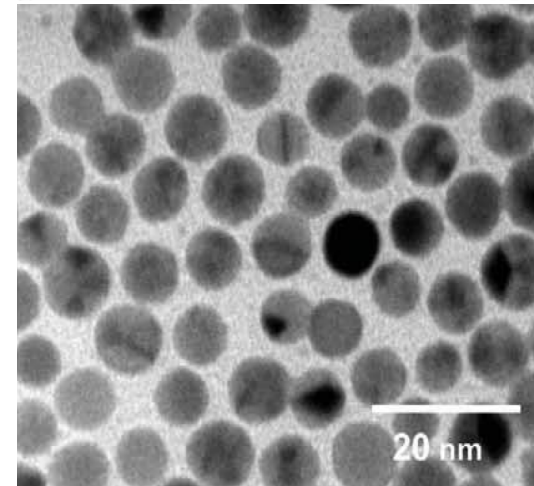

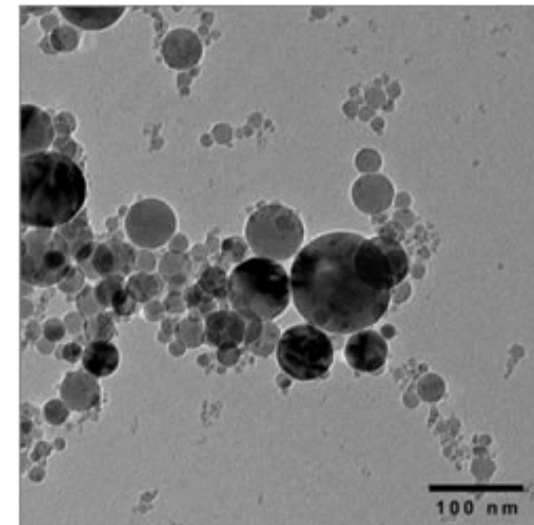

## Cause

- Low thermal conductivity conventional materials
- Liquid cooling has reached its limits

# Nanofluids

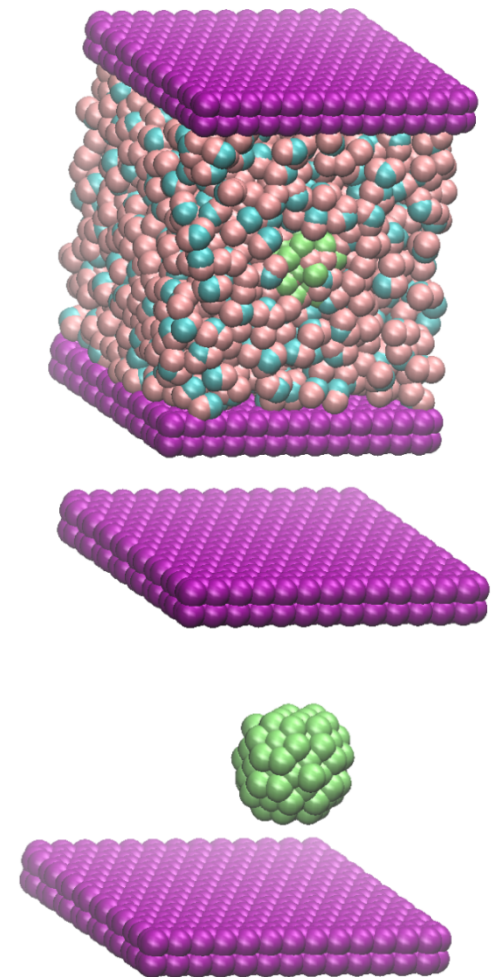

- ❑ Suspensions of solid particles with nanometer size diameters in a fluid
- ❑ Nanofluids have enhanced thermal properties
- ❑ Physical explanation and theoretical models are a topic of debate

# Nanofluid

## **Water-Copper nanofluid, confined in graphene walls**

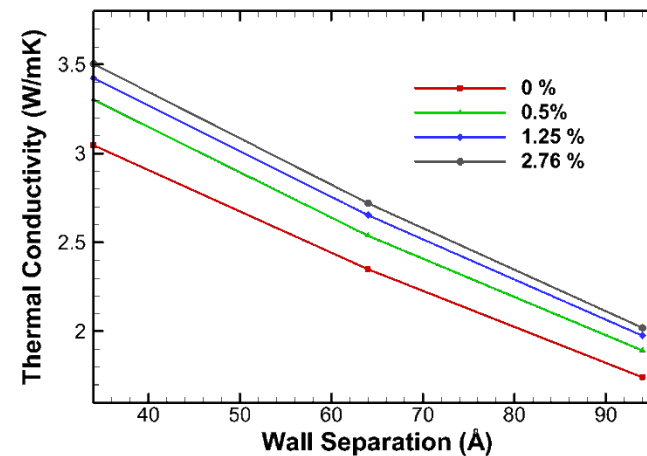

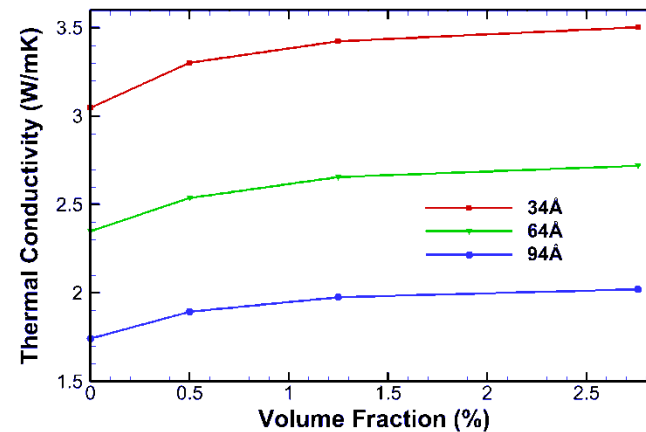

- Thermal conductivity was calculated for various wall separation distances for different volume fractions.

# Nanofluid

## Thermal conductivity

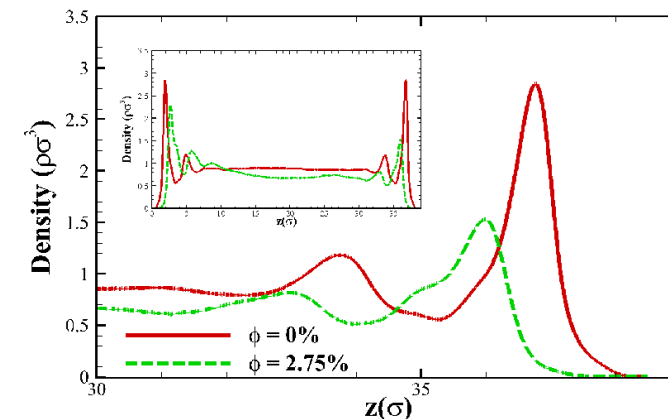

- Increases with increasing volume fraction
- All curves have similar shape
- As the wall separation distance decreases, the thermal conductivity for all particle loadings experiences a jump

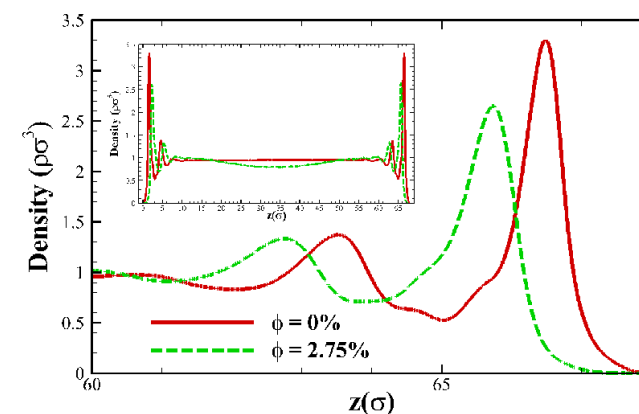

# Nanofluid

## Particle affects structure of liquid atoms

- Graphene is hydrophobic
- Addition of particle attracts the density layers at the solid/liquid interface
- The smaller the channel is the more effect the particle has to the solid-liquid interface
- In turn the thermal conductivity is affected

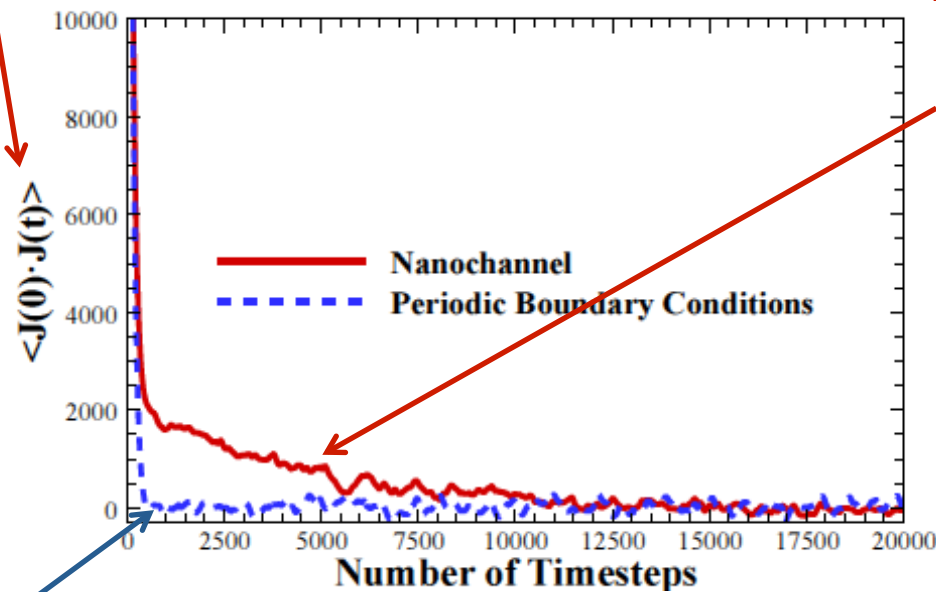

**34Å Channel width**

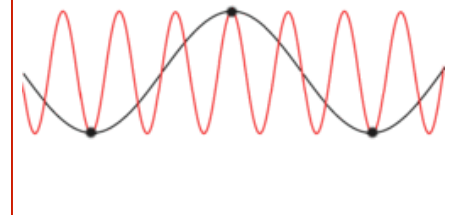

**94Å Channel width**

# Ballistic heat transfer

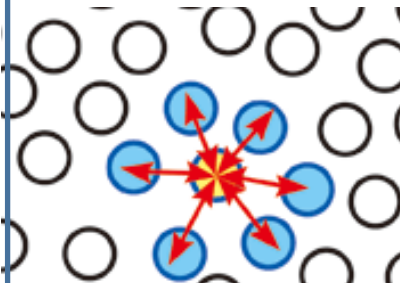

$$\lambda = \frac{1}{3k_BVT^2} \int_0^t \langle q(0) \cdot q(t) \rangle dt$$

Ballistic heat transfer

Diffusive heat transfer

# Concluding remarks

- ❑ High-order CFD has significant potential for addressing design challenges
- ❑ MD and multi-scale modelling can provide new insights into small scale phenomena that can enable the development of new technologies.
- ❑ Hybrid molecular-continuum methods for solids and fluids are capable of resolving physics on micro/nano scale
- ❑ Research into the development of more accurate and efficient methods as well as software redesign need to go hand-in-hand with the High Performance Computing advancements
